We theoretically and numerically analyze thermal invisibility based on the concept of scattering cancellation and mantle cloaking. We show that a small object can be made completely invisible to heat diffusion waves, by tailoring the heat conductivity of the spherical shell enclosing the object. This means that the thermal scattering from the object is suppressed, and the heat flow outside the object and the cloak made of these spherical shells behaves as if the object is not present. Thermal invisibility may open new vistas in hiding hot spots in infrared thermography, military furtivity, and electronics heating reduction.

The realization of electromagnetic invisibility cloaks¹–⁴ is undoubtedly one of the most exciting and challenging applications of metamaterials⁵. In the previous decades, thanks to the astonishing development of micro- and nano-fabrication and 3D printing, this goal has got closer to reality. In 2005, Alù and Engheta proposed a transparency device that relies on the so-called scattering cancellation technique (SCT). This mechanism consists of using a low or negative electric permittivity cover to cancel the different scattering multipoles of the object to hide. This class of cloaking devices has been shown to be quite robust to changes in the geometry of objects and the frequency of operation⁶–⁹. Moreover, a recent experimental study has shown that these cloak designs can actually be realized at microwave frequencies¹⁰. Applications in furtivity, non-invasive sensing, and probing can be envisaged¹¹–¹³, opening new directions in medicine, defense, and telecommunications. Recent findings also suggest that objects can be made invisible using the mantle cloaking technology, where a metasurface can produce similar effects with a simpler and thinner geometry. This is achieved by tailoring the surface current on the metasurface and consequently the phase of re-radiated fields¹³–¹⁶. It should also be mentioned here that other cloaking techniques have been put forward in the recent years based on various concepts such as conformal mapping¹, transformation optics², homogenization of multistructures³–⁸, active plasmonic cloaks⁹, anomalous localized resonances¹⁰, and waveguide theory¹¹.

The concept of invisibility has been extended to other realms of physics. Cloaks capable of hiding objects from acoustic waves¹²–¹⁵, surface water waves¹⁶, flexural bending waves¹⁷, seismic waves¹⁸–¹⁹, quantum matter waves¹⁰,₂¹ and even diffusive light propagation²²,²³ have been developed. And more recently, after the seminal work of Guenneau et al.²⁴, invisibility cloaks for heat waves has become another exciting venue for cloaking applications²⁵–²⁷. Thermal cloak designs inspired by transformation optics² have been subsequently proposed²⁸–⁴⁰ to control the flow of heat in metamaterial structures. Their experimental validation followed shortly²¹–²⁴. Thermal cloaking may find interesting applications in modern electronics. It can be used to reduce the heat diffused from computers or to protect a specific nano-electronic component by re-directing the flow of heat. This technique can also be used for isolation in buildings to reduce the consumption of energy required in heating or cooling.

In this paper, we propose to use the concept of scattering cancellation to generate the invisibility effect for heat diffusion waves. The peculiarity of our cloak is that, unlike earlier designs, we consider both static and time-harmonic dependence (note that time-harmonic heat sources can be generated using pulsating lasers⁴³). This scenario requires cancellation of two scattering orders for small objects, i.e. the monopole and dipole ones, corresponding to the specific heat capacity and the heat conductivity, respectively. Numerical simulations confirm that a scattering reduction of over 40 dB can be obtained for optimized cloak parameters. Additionally, it is shown that the proposed cloak suppresses both the near and far heat fields. We also demonstrate that coating an object with an ultra-thin layer or thermal metasurface is a viable way for scattering reduction (mantle cloaking).
Results

Heat diffusion waves and their dispersion relation. Using the first principle of thermodynamics in a closed system, one can show that in the absence of radiation and convection, the temperature of a physical system obeys the Fourier law \( \nabla \cdot j_0 + \rho c \partial T / \partial t = Q \). Here, \( j_0 = \rho \) and \( T \) represent the density of heat flux (heat flow per unit surface per unit time), the density of the fluid, and the temperature field, respectively. \( c \) is the specific heat capacity and \( Q \) denotes the heat energy generated per unit volume per unit time (Fig. 1). Using the Fourier law, i.e. the linear and instantaneous temperature field, respectively.

For a constant conductivity and in the absence of heat sources, Eq. (1) simplifies to \( \partial T / \partial t = k / (\rho c) \Delta T \). To solve this equation, one can assume that \( T(r, t) = \Re(\tilde{T}(r, t)) \), with \( \tilde{T}(r, t) = T_0 e^{ik r - i\omega t} \), where \( k \) is the wave number of the pseudo diffusion plane wave and \( \omega \) its angular frequency. This ansatz is valid, only because Eq. (1) is a linear equation, meaning that \( T \) is a solution, if and only if, \( \tilde{T} \) is a solution. The dispersion relation of heat diffusion waves is thus \( i\omega = k^2\kappa / \rho c \). If one assumes that \( \omega \) is real, then \( k = \pm (1 + i) / \delta \), with \( \delta = \sqrt{2k/\rho c\omega} \). The general solutions are thus attenuated diffusing plane waves. Now, under the assumption of time-harmonic dependence \( e^{-i\omega t} \), generated for instance by a pulsating laser, and constant conductivity, Eq. (1) simplifies to

\[
\Delta T + k^2 T = -Q / \kappa.
\]

For the structure in Fig. 1, Eq. (1) is supplied with two boundary conditions that should be satisfied at the surface of both spherical object and the cloak. Across the boundaries \( r = a_1 \) and \( r = a_2 \), we have the continuity of the temperature and the density of heat flux, i.e. \( T_{r=a_2} = T_{r=a_1} \), and \( (k\partial T / \partial n)|_{r=a_2} = (k\partial T / \partial n)|_{r=a_1} \), where the signs + and − refer respectively to the inner and outer regions, and \( \partial / \partial n \) denotes the normal derivative, which only depends upon the radial coordinate in the case of circular objects. Here, \( a_1 \) and \( a_2 \) are the inner and outer radii of the shell. Moreover, \( \{\kappa_1, \rho_1, c_1, k_1\}_{n=0,1,2} \) represent the conductivity, fluid density, heat capacity, and wave number in the background medium \( (r>a_2) \), object \( (r<a_1) \), and shell \( (a_1<r<a_2) \), respectively.

Scattering cancellation technique for heat diffusion waves: static regime. The aim of this study is to show that scattering from various spherical objects can be reduced drastically by carefully choosing the values of the shell conductivity and the specific heat capacity. First, a spherical object centered at the origin of a spherical coordinate system is considered. Two parallel plates set at different temperatures \( T_1 < T_2 \), generate a heat flux (plane heat diffusion wave) that impinges on the scattering object [Fig. 1(a)]. In this first section, the case of static (steady-state) regime is considered, i.e. \( \partial T / \partial t = 0 \). So Eq. (1) is simplified to \( \Delta T + Q / \kappa = 0 \). The scalar temperature field \( T \) in the different regions of space can be expressed in spherical coordinates (Fig. 1) as,

\[
T(r, \theta) = \sum_{l=0}^{\infty} A_l r^l P_l(\cos \theta), 0 < r < a_1, \tag{3}
\]

\[
T(r, \theta) = \sum_{l=0}^{\infty} [B_l r^l + C_l r^{-l-1}] P_l(\cos \theta), a_1 < r < a_2, \tag{4}
\]

\[
T(r, \theta) = \sum_{l=0}^{\infty} [E_l r^l + D_l r^{-l-1}] P_l(\cos \theta), r > a_2, \tag{5}
\]

where \( P_l(\cdot) \) represents the Legendre polynomial of order \( l \). For \( r \to \infty \), \( T(r > a_2) = -Q / \kappa \), therefore \( E_l = -Q / \kappa \) and all the other coefficients \( B_l, C_l, D_l \) are zero. The remaining coefficients are obtained by solving the linear system

\[
\begin{pmatrix}
 1 & 1 & 1 / a_1^3 & 0 \\
 k_1 & k_2 & -2k_2 / a_1^2 & 0 \\
 0 & 1 & 1 / a_2^3 & 1 / a_2^2 \\
 0 & k_2 & -2k_2 / a_2^2 & 2k_2 / a_2^3 \\
\end{pmatrix}
\begin{pmatrix}
 A_1 \\
 B_1 \\
 C_1 \\
 D_1 \\
\end{pmatrix}
= \begin{pmatrix}
 0 \\
 0 \\
 Q / \kappa \\
 Q \\
\end{pmatrix}, \tag{6}
\]

which is obtained by applying the continuity conditions at the boundaries \( r = a_1 \) and \( r = a_2 \). The scattering cancellation condition is obtained by enforcing that the first scattering coefficient \( D_1 \) is zero,

\[
D_1 = Q / \kappa \frac{(k_0 - k_2) (k_1 + 2k_2) - \sqrt{(k_0 - k_2) (k_1 + 2k_2)}}{(k_0 + 2k_2) (k_1 + 2k_2)} = 0, \tag{7}
\]

where \( y = a_1 / a_2 \). Solving Eq. (7) for \( k_2 \) yields the value of the shell conductivity, which ensures that there is no temperature perturbation with a uniform temperature gradient, as if the object does not exist,

\[
k_2 = \frac{\kappa_0 - k_1}{(2k_0 - 2k_1) / \kappa_0 + (2k_0 - k_1) / \kappa_1 + \sqrt{(2k_0 - k_1) / \kappa_0 + (2k_0 - k_1) / \kappa_1 + 8k_0 k_1 / (\kappa_0 - \kappa_1)^2}}. \tag{8}
\]

Scattering cancellation technique for heat diffusion waves: time-harmonic regime. The scattering coefficients relate the scattered fields to the incident ones, and depend on the geometry of the object and the frequency \( \omega \). Moreover, for a given size \( a \) of the object, only contributions up to a given order \( l_0 \) are relevant, since the amplitude of the scattering coefficients changes as \( \omega (k_0 a)^{l_0 + 1} \). The incident heat excitation is an oblique plane diffusion wave, of incidence angle \( \theta \), and is of the form \( e^{ik_0 r \cos \theta} \). In a spherical coordinate system, it can be expressed as

\[
T^{inc}(r, \theta) = T_0 \sum_{l=0}^{\infty} [i (2l + 1) j_0(k_0 r) P_l(\cos \theta)], \tag{9}
\]

where \( j_l \) denotes the \( l \)-th spherical Bessel function and \( T_0 \) is the amplitude of the incident temperature field. The scattered field \( (r > a_2) \) can be expressed in a spherical coordinate system as

\[
T^{scat}(r, \theta) = T_0 \sum_{l=0}^{\infty} [i (2l + 1) j_l(k_0 r) P_l(\cos \theta)], \tag{10}
\]
where $s_i$ are the complex scattering coefficients and $h_l^{(1)}$ are spherical Hankel functions of the first kind. Therefore, the temperature field can be expressed in the different regions of space as

$$T(r, \theta) = T_0 \sum_{l=0}^{\infty} a_{lj}(k_l r) P_l(\cos \theta), 0 < r < a_1,$$

$$T(r, \theta) = T_0 \sum_{l=0}^{\infty} [b_{lj}(k_l r) + c_l y_l(k_l r)] P_l(\cos \theta), a_1 < r < a_2,$$

$$T(r, \theta) = T^{\text{inc}} + T^{\text{scat}}$$

$$= T_0 \sum_{l=0}^{\infty} i(2l+1) \left[ j_l(k_l a_1) + s_l h_l^{(1)}(k_l a_1) \right] P_l(\cos \theta), r > a_2,$$

with $a_1$ and $(b_l, c_l)$ complex coefficients of the temperature field inside the object and the shell, respectively. Applying the continuity conditions at the boundaries $r=a_1$ and $r=a_2$ yields the different coefficients. In particular, $s_l = -U_l/(U_l + iV_l)$. Here $U_l$ and $V_l$ are given by the determinants

$$U_l = \begin{vmatrix} j_l(k_l a_1) & y_l(k_l a_1) & -j_l(k_l a_1) & 0 \\ j_l(k_l a_2) & y_l(k_l a_2) & 0 & j_l(k_l a_2) \\ k_2 k_3 j_l(k_l a_3) & k_2 y_l(k_l a_3) & -k_1 k_3 j_l(k_l a_1) & 0 \\ k_2 k_3 j_l(k_l a_3) & k_2 y_l(k_l a_3) & 0 & k_0 k_3 j_l(k_l a_2) \end{vmatrix},$$

and

$$V_l = \begin{vmatrix} j_l(k_l a_1) & y_l(k_l a_1) & -j_l(k_l a_1) & 0 \\ j_l(k_l a_2) & y_l(k_l a_2) & 0 & j_l(k_l a_2) \\ k_2 k_3 j_l(k_l a_3) & k_2 y_l(k_l a_3) & -k_1 k_3 j_l(k_l a_1) & 0 \\ k_2 k_3 j_l(k_l a_3) & k_2 y_l(k_l a_3) & 0 & k_0 k_3 y_l(k_l a_2) \end{vmatrix}.$$

The scattering cross-section (SCS) $\zeta^{\text{scat}}$ is a measure of the overall visibility of the object to external observers. It is obtained by integrating the scattering amplitude $g(\theta)$, defined such that $T^{\text{scat}}/T_0 = g(\theta)/r^{k_0 a_1}$, for $r \to \infty$,

$$\zeta^{\text{scat}} = \int d\Omega |g(\theta)|^2.$$

Here, $d\Omega$ is the incremental solid angle, in spherical coordinates, $d\Omega = 2\pi \sin \theta \, d\theta d\phi$, and $g(\theta)$ is expressed as

$$g(\theta) = -i \sum_{k_0}^{\infty} (2l+1) s_l P_l(\cos \theta).$$

Inserting Eq. (17) into Eq. (16) yields

$$\zeta^{\text{scat}} = \frac{4\pi}{|k_0|^2} \sum_{l=0}^{\infty} (2l+1)|s_l|^2.$$

In the quasistatic limit (long diffusion length $k_0 a_1 \ll 1$), only few scattering orders contribute to the overall scattering cross-section, namely the first two orders ($l=0$ for the monopole, and $l=1$ for the dipole mode, unlike in the electrodynamic case, where the first dominant mode is the dipole one). In this scenario, one has

$$\zeta^{\text{scat}} \approx \frac{4\pi}{|k_0|^2} (|s_0|^2 + 3|s_1|^2).$$

Consequently, canceling these two modes, i.e. $s_0 = 0$ and $s_1 = 0$, will ensure that $\zeta^{\text{scat}} = 0$, and the thermal scattering from the object will be suppressed. Namely, the SCT conditions on the parameters of the cloaking shell $k_2, \rho_2, c_2$, and $a_2$ are

$$\frac{\rho_2 c_2 - \rho_0 c_0}{\rho_2 c_2 - \rho_1 c_1} = \left(\frac{a_2}{a_1}\right)^3 = \gamma^3, \text{ for } s_0 = 0,$$

and

$$\frac{(k_0 - k_2)(k_1 + 2k_2)}{(k_1 - k_2)(k_1 + 2k_2)} = \gamma^3, \text{ for } s_1 = 0.$$

The monopole SCT condition in Eq. (20), depends only on the product of the density and the specific heat of the shell, and the ratio of radii of the object and the shell $\gamma$. Similarly, the condition in Eq. (21) depends only on the conductivity of the shell and $\gamma$. By enforcing these two conditions, the total scattering from the spherical object can be suppressed in the quasistatic limit.

Figures 2(a) and 2(b) illustrate numerical solutions to Eqs. (20) and (21), where the variation of the relative specific heat capacity $\rho_2 c_2 / \rho_0 c_0$ and the relative heat conductivity $k_2 / k_0$ are plotted versus $\gamma$ and $\rho_1 c_1 / \rho_0 c_0$ and $k_1 / k_0$, respectively. From the solution of Eq. (20), given in Fig. 2(a), one can see that the required relative heat conductivity of the shell $k_2 / k_0$ needs to be almost always negative, for varying $\gamma$ and $k_1 / k_0$. However, for an object with small heat conductivity and small radius [lower part of Fig. 2(b), in blue color], the required shell conductivity is close to zero. In fact, from Eq. (21), one can derive that for the negative solution of Eq. (21)

$$k_2 / k_0 = \frac{\pi}{\sqrt{2\pi k_1 (1 - \gamma^3)^{-2} / 4(1 - \gamma^3)}},$$

where $\pi = 2 + \gamma^3 - (1 + 2\gamma^3) k_1 / k_0$. It can be clearly seen that for positive conductivities of the object, the condition $k_2 / k_0 < 0$ has to be satisfied to achieve the optimal heat cloaking effect.

Let us move now to the analysis of a specific scenario, where the heat scattering of a spherical object is characterized. The relative specific heat capacity of the object is $\rho_1 c_1 / \rho_0 c_0 = 1.25$ and its relative conductivity is $k_1 / k_0 = 0.5$. The radius of the object $a_1 = 1$, and the wave numbers are normalized to $a_1$. The free space wave number is chosen as $k_0 a_1 = 0.5$. This object is coated with a shell of outer radius $a_2 = 1.1 a_1$. $\zeta^{\text{scat}}$ of the total object-shell structure, defined in Eqs. (16)–(18), is normalized to the SCS of the bare object, and plotted against varying values of $\rho_2 c_2 / \rho_0 c_0$ and $k_2 / k_0$. The result is shown in Fig. 3(a) in logarithmic scale. The blue regions correspond to significant scattering reduction, whereas red regions correspond to enhanced scattering from the structure. It can be noticed that ranges of $k_2 / k_0$ between 1 and 4, and $\rho_2 c_2 / \rho_0 c_0$ between 0.05 and 0.5, are best for thermal scattering cancellation (now using the positive solution of Eq. (21), for practical realizations). The white dot has coordinates (3.1, 0.15) that correspond to the theoretical SCT condition obtained from Eqs. (20) and (21). It is also interesting to note that numerical simulations taking into account many scattering orders, give scattering reduction of 40 dB, sensibly around the same point.

These results show the importance of taking into account both the shell conductivity and specific heat capacity, in contrast to previous studies that only considered the effect of conductivity through the static analysis. This can be better understood from Figs. 3(b) and 3(c), where the normalized SCS is plotted versus $k_2 / k_0$ for various values of $\rho_2 c_2 / \rho_0 c_0$ and versus $\rho_2 c_2 / \rho_0 c_0$ for various values of $k_2 / k_0$, respectively. The sensitivity to variations in $k_2 / k_0$ is more evident from these figures, since a small variation from the optimum value
results in fast deterioration of the scattering reduction: when $\kappa_2/\kappa_0$ is equal to 1 or 5, there is no dip in the SCS and the scattering is high, as can be seen from Fig. 3(c). The sensitivity to variations in $\rho_2 c_2/\rho_0 c_0$ is less important, as can be seen from Fig. 3(b), but it is important to choose values around those predicted by Eqs. (20) and (21). On the other hand, when $V_1=0$, peaks corresponding to modal resonances start appearing in the scattering cross-section (related to Fano-like response of the system due to interference between dark and bright scattering modes)\(^{14}\).

To better illustrate the efficiency of the proposed cloak, the far-field scattering patterns, i.e. the heat scattering amplitude $|g(\theta)|$ in polar coordinates, in the $x$–$y$ plane, are shown in Figs. 4(a) and 4(b). These figures demonstrate that the object is almost undetectable at all angles with scattering amplitude orders of magnitude lower than that of the bare object. As a result, there is no temperature perturbation around the object immersed in the thermal fields. To further demonstrate the functionality of the cloak, Figs. 4(c) and 4(d) plot the amplitude distribution of the scattered thermal field when the heat from the infinite sheet of oscillating heat source is impinging from left to right on the structure, without and with the cloaking shell, respectively. When the object is cloaked, the field amplitude is constant everywhere in space in contrast to the case of the object without the cloak.

**Discussion**

Mantle cloaking for heat diffusion waves. As stated in the introduction, recent findings suggest that objects can be made invisible using the surface cloaking technology, where a metasurface may produce similar cloaking effects in a simpler and thinner geometry\(^{13–16}\). The ultrathin mantle cloak with an averaged surface reactance metasurface\(^{13}\) reduces the scattering from the hidden object, comparable to bulk metamaterial cloaks. The setup of the problem is similar to the previous section, except for the fact that scattering cancellation is achieved by a surface, instead of a shell. This is illustrated in the inset of Fig. 5(a). The impedance boundary condition results in jumps in the radial component of the density of heat flux, on the interface between the two media.

In what follows it is shown that the scattering from various spherical objects can be drastically reduced by choosing the appropriate
surface impedance, and thus their visibility to heat diffusion waves can be suppressed.

To design a mantle cloak, we keep the boundary conditions at \( r = a_1 \) same as those in the previous sections, while we replace the boundary conditions at \( r = a_2 \) with

\[
T_{r=a_2} = T_{r=a_2} = T_{r=a_2},
\]

\[
\frac{1}{k_0} \left( \frac{k}{\epsilon} \right)^{\frac{r}{a_2^2}} = Z_s^{-1} T_{r=a_2}.
\]

Eq. (24) is a surface impedance condition that implies a jump in the density of heat flux. Here, \( Z_s = R_s + iX_s \) is the averaged surface impedance that relates the temperature to the density of heat flux on the surface.

Following the procedure described in the previous section, with these new boundary conditions, one can show that the 4th spherical scattering harmonic can be suppressed, provided that the following determinant is canceled,

\[
\begin{vmatrix}
   j(k_0a_1) & y(k_0a_1) & -j(k_1a_1) & 0 \\
   k_0 j(k_0a_1) & k_0 y(k_0a_1)/\rho_0 & \kappa_1 k_0 j(k_1a_1) & 0 \\
   j(k_0a_2) & y(k_0a_2) & 0 & j(k_0a_2) \\
   k_0 j(k_0a_2) & k_0 y(k_0a_2)/\rho_0 & \kappa_1 k_0 j(k_1a_2) & 0 \\
   +j\psi j(k_0a_2) & +\psi y(k_0a_2) & 0 & j(k_0a_2) \\
\end{vmatrix} = 0.
\]

It should be noted that for the mantle cloak design considered here, \( k_2 = k_0 \) and \( \rho_2 = \rho_0 \). In Eq. (25), the dimensionless function \( \psi \) is defined as

\[
\psi = \frac{i\alpha Z_s^{-1}}{k_0 k_0} = \frac{Z_s^{-1}}{k_0 k_0}.
\]

For \( k_0 a_2 \ll 1 \), the spherical Bessel functions take a simpler polynomial form, and the approximate cloaking condition in this limit can be written as

\[
X_s = \frac{2k_0}{3\gamma^{\frac{1}{3}}} \left( \gamma^2 + \frac{\kappa_0 + 2k_1}{\kappa_1 - k_0} \right).
\]

This clearly shows that by properly choosing the thermal surface reactance (expressed in units of \( \frac{\text{m}^2}{\text{K}} \)), it is possible to suppress the dominant multipolar scattering in the quasistatic limit.

Figure 5(a) plots the SCS versus \( X_s \) for cloaked objects with various \( \gamma \). The SCS of a bare object is plotted for comparison. For \( X_s \rightarrow \infty \), we notice that the metasurface does not reduce the scattering, consistent with the limit of no-surface. For specific values of \( X_s \), however, a relevant scattering reduction is achieved, and this may be obtained for different values of \( a_2 \), even in the limit of a cloak winding conformal to the object \( a_2 = a_1, \gamma = 1 \).

Figure 5(b) plots the SCS versus the frequency for cloaked objects with \( a_2 = a_1 \) (conformal) and \( a_2 = 1.1a_1 \). We suppose here that the surface reactance does not vary with frequency and is given with \( X_s = 1.36 \times 10^{-7} \) for \( \gamma = 1 \) and \( X_s = 1.62 \times 10^{-7} \) for \( \gamma = 0.9 \). The

![Figure 4](https://example.com/figure4.png)

**Figure 4 | Near and far-field characterization.** Analytical scattering amplitude \( |g(\theta)| \), given by Eq. (17), in polar coordinates, and in logarithmic scale (a) for the bare object with \( k_1/k_0 = 0.5 \) and (b) for the cloaked object, with \( k_2/k_0 = 3.1 \). Amplitude of the oscillating temperature in the near-field of (c) the same bare object of Fig. 4(a) and (d) the same cloaked object of Fig. 4(b) for \( k_0 a_1 = 0.5 \). Arrows show the direction of \( \nabla T \) and the color bar denotes the plot of \( |T/T_{\text{mc}}| \).
Analytical methods based on scattering Mie theory of spherical thermal scatterers are used to obtain the results presented in Figs. 2, 3, 4(a), 4(b), and 5. In the quasistatic limit, where the size of the object is much smaller than the wavelength and only the lowest-order Mie coefficients are kept, analytical formulas are obtained [Eqs. (20) and (21)]. Those give results similar to the ones obtained from full Mie series solutions [Fig. 3(a)]. The results given in Figs. 4(c) and 4(d) are obtained using COMSOL Multiphysics software, which solves Eq. (2) with proper boundary conditions using a finite element scheme.

Figure 5 | Thermal mantle cloaking. Normalized (analytical) SCS $\xi^{\text{out}}$ versus $X_s 10^{-7}$ for the object with normalized radius $k_0a_1 = 0.5$ and relative heat conductivity $k_1/k_0 = 0.1$ for various values of the ratio $\gamma$. (b) Normalized SCS $\xi^{\text{out}}$ versus normalized frequency for the same object with $X_s = 1.36 \times 10^{-7}$ and $k_1 = 1.62 \times 10^{-7}$ for values of the ratio $\gamma = 1$ and $\gamma = 0.9$. The inset of Fig. 5(a) illustrates the object coated with a thermal metasurface, projected in the $x$–$y$ plane. Amplitude of the temperature field on the $x$–$y$ plane for the same object (c) with mantle cloak with $X_s = 1.62 \times 10^{-7}$ and (d) without the cloak. The color bar denotes the plot of $|T/T^{\text{inc}}|$.

SCS of uncloaked objects with radius $r = a_1$ and $r = 1.1a_1$ are plotted for comparison. It is evident that excellent scattering reduction may be achieved over a large range of frequencies for both cases.

Figures 5(c) and 5(d) plot the amplitude of the temperature field scattered by a cloaked and uncloaked object, on the $x$–$y$ plane at a time instant, respectively. When the object is cloaked, both forward and backward scattering almost vanish. This reduction of scattering is achieved due to the proper choice of the surface impedance, which restores almost uniform amplitude all around the cloak.

Summary. In conclusion, we have proposed an original route towards designing thermal cloaks based on the scattering cancellation technique. This technique is inspired by the plasmonic cloaking, which makes use of shells with induced negative polarization to suppress scattered electromagnetic fields. And contrary to invisibility cloaks based on transformation optics, SCT offers simple cloaking designs (without the need of anisotropy and inhomogeneity of the physical parameters).

One may envision that using this design may further make the thermal cloaking closer to its practical and feasible realization. We believe that such a structured cloak could be manufactured within current technology, having in mind some potential applications in invisibility, sensing and thermography. The range of industrial applications is vast, and proof of concept should foster research efforts in this emerging area of thermal cloaks and metamaterials.

Methods

Analytical methods based on scattering Mie theory of spherical thermal scatterers are used to obtain the results presented in Figs. 2, 3, 4(a), 4(b), and 5. In the quasistatic limit, where the size of the object is much smaller than the wavelength and only the lowest-order Mie coefficients are kept, analytical formulas are obtained [Eqs. (20) and (21)]. Those give results similar to the ones obtained from full Mie series solutions [Fig. 3(a)]. The results given in Figs. 4(c) and 4(d) are obtained using COMSOL Multiphysics software, which solves Eq. (2) with proper boundary conditions using a finite element scheme.

**Acknowledgments**

This work is partially funded by King Abdulaziz City for Science and Technology (KACST) TIC (Technology Innovation Center) for Solid-state Lighting at KAUST. P.-Y.C. would like to acknowledge fruitful discussion with David Pich, S.G. would like to acknowledge a funding of the European Research Council through ERC grant ANAMORPHISM.

**Author contributions**

M.F. and P.-Y.C conceived the idea of this study. M.F. performed numerical simulations and wrote the manuscript. P.Y.C., H.B., C.A., S.G., and A.A. contributed to the analysis of the results and reviewed the manuscript. S.G. and A.A. supervised the project.
