Abstract

In this work, ZnO thin films were synthesized on the surface of copper electrodes by an electrochemical method at different deposition potentials -0.6, -0.8, -1 and -1.2 V versus SCE. The as-prepared ZnO modified Cu electrodes (ZnO/Cu) have been employed for electrocatalytic nitrate reduction under neutral pH (pH = 6.8) condition in 0.1 M KNO₃ using cyclic voltammetry and amperometry techniques. The electrode surface and structure were investigated by scanning electron microscopy (SEM) and X-ray diffraction (XRD) techniques. The effects of the electrodeposition potential and time on the morphology, structure and electrocatalytic properties were studied. The results show that under optimized ZnO electrodeposition conditions, the ZnO/Cu electrode exhibits interesting electrocatalytic performance in nitrate reduction. A well defined and reproducible peak with maximum current density was obtained for ZnO/Cu electrode elaborated at -1V for 20 min electrodeposition time. Kinetic study by chronoamperometry is indicative of ammonia formation.

Keywords: ZnO; Electrodeposition; Copper; Electrocatalysis; Nitrate reduction

1. INTRODUCTION

Nitrate reduction and determination is extremely important for environment and public health issues. The development of specific analytical methods for the detection and destruction of nitrate is of great importance to limit pollution of the natural environment. Many methods are used to remove NO₃⁻ ions from contaminated water, such as reverse osmosis, photocatalytic, biochemical, chemical and electrochemical reduction [1-4]. Most of them involving complicated and time-consuming procedures. In contrast, electrochemical nitrate treatment
can offer a promising and attractive solution due to its advantages regarding low cost effectiveness, convenience, ability to treat highly concentrated nitrate effluents and environmental friendliness [5, 6].

As the products of the nitrate electroreduction are critically dependent on the nature of the cathode material [7, 8], several simple metal electrodes (Nickel, Platinum, Graphite, Glassy carbon, Copper, etc.) have been widely used for the reduction of nitrate [9-14]. Compared to other materials, Cu metal has shown good catalytic character for nitrate reduction [15-17]. However, the use of bare electrodes for the reduction of nitrate requires high potentials [18, 19] and these electrodes tend to be poisoned by the species formed during the electrochemical process [20]. This considerable drawback limits their use for large scale applications. A good way of lowering the reduction potential and limiting surface poisoning is the use of modified electrodes and their application has received considerable attention in recent years due to many advantages, such as wider operational potential window, easy manufacture, low price, renewable surface and longer life time [21-23]. In the other hand, ZnO are the object of quickly growing in the last few years, due to its number of exciting properties [24-26]. It is a wide band gap semiconductor material with $E_g \approx 3.3$ eV and large excitonic binding energy of $\sim 60$ meV [27]. Also, it’s an environmentally friendly material that does not form toxic byproducts [28], with low price, high chemical and thermal stability. Due to these excellent properties, ZnO nanomaterials have been used as efficient electron mediators for the fabrication of electrochemical sensors. The electrochemical reduction of nitrate ions has been investigated over a large number of modified electrodes, for example, metals modified electrode [29, 30] and polymer modified electrode [31]. To our knowledge, fewer research articles have been published on electrocatalytic activity of ZnO toward nitrate reduction. The main objective of the present study is to elaborate ZnO modified copper electrode by electrodeposition method and we have reported the applicability of a ZnO/Cu electrode for the selective reduction of $\text{NO}_3^-$ under neutral pH condition. The electrocatalytic activity of the as-prepared Cu–ZnO electrode is compared with that of a pure Cu surface.

The electrocatalytic ability of ZnO/Cu was thoroughly investigated by cyclic voltammetry (CV) and chronoamperometry.

2. Materials and methods

2.1. Reagents and solutions

All chemicals were of analytical-reagent grade from Merck or Fluka and were used directly without further purification. All aqueous solutions were prepared with bi-distilled water
(presenting high resistance ~ 18 MΩ). The supporting electrolyte used in all the experiments was 0.1 M KNO₃ or 0.1 M phosphate buffer solutions.

2.2. Apparatus

All the electrochemical experiments were carried out using a potentiostat/galvanostat (Autolab PGSTAT30) coupled with HP computer under “Voltamaster logiciel”. The electrochemical cell was assembled with a conventional three-electrode system: a bare Cu or ZnO/Cu were employed as working electrodes. Platinum wire is used as auxiliary electrode and a saturated calomel electrode (SCE) as reference. The surface morphology of the modified electrode was investigated by a scanning electron microscope (SEM) (Hitachi, S-570). The Si-Li electrode was used for light elements with a 133 eV resolution at low counting rate and beam parameters of 20 keV and 160 pA. X-ray diffraction (XRD) analyses were performed on a Siemens D5000 diffractometer using filtered CuKα (λ= 0.15406 nm) as a radiation source. The diffractometer was operated at 40 kV, room temperature, with a scanning rate of 10 min⁻¹.

2.3. Preparation of the synthesized ZnO/Cu electrode

A wet electrochemical method was employed for the synthesis of ZnO thin film. ZnO thin films were deposited from an electrolyte containing 5. 10⁻³ M Zn(NO₃)₂, 6H₂O and 0.1 M KNO₃ at 70°C using a different potentials -0.6, -0.8, -1 and -1.2V/SCE and at different deposition times 5, 10, 15, 20, 25 and 30 min. The pH of solution is fixed at 6. Before the electrodeposition process, the massive Cu were polished using emery paper with 1200 grit, degreased with acetone, cleaned with twice distilled water and dried with a soft tissue paper. This Cu electrode was then used as the working electrode in the electrodeposition of ZnO on a copper electrode.

3. RESULTS AND DISCUSSION

3.1. Electrochemical study by cyclic voltamperometry and chronoamperometry

Prior to the development of ZnO by chronoamperometry, we found it useful to consider the voltammetric behavior of ZnO deposit. The cyclic voltammetry study was performed in a potential range of -0.5 to -1.6 V versus SCE onto copper substrate. The potential scan was initiated in the negative direction from the open circuit potential (OCP) at a scan rate of 8 mVs⁻¹ (Fig. 1). As stated in our previous works [25], the ZnO reaction formation is initiated by the nitrate reduction reaction. We can see in Fig. 1 that the current begins to increase for a potential of -0.2 V indicating that the reaction of nitrate reduction on the copper substrate is
very active leading to ZnO deposit at very low cathodic potentials. Below -0.6 V, the cathode current increases faster with the potential increase indicating the activation of the ZnO formation process. However, the rapid increase in intensity at -1.25 V corresponds to the water reduction reaction. No anodic peak appears in the return sweep, indicating that no zinc metal is codeposited with ZnO.

Accordingly to the voltammetric study, ZnO may be deposited at low cathodic potential as -0.2 V and high deposition rate will be reached for a potential values more cathodic than -0.6 V; thus a large potential window from -0.6 V to -1.2 V versus SCE was chosen to deposit ZnO thin films on Cu substrate using chronoamperometry, in solution containing 5 mM of Zn (NO$_3$)$_2$ and 0.1 M KNO$_3$. The applied potentials correspond to the maximum peak for ZnO deposit, readings from the previous figure. The obtained current transients curves are illustrated in Fig.2. We can see that after an initial sharp peak the current decreases rapidly in the first few seconds due to the charge of the double layer which can be accompanied by the adsorption of ZnO at the interface. After this, the current stabilize to form a plateau corresponding to the stability of ZnO. Also, we can see that an increase in cathodic potential was accompanied by an increase in cathodic plateau. It is worth noting that increasing applied potential leads to the increase in zinc oxide deposition current densities.

3.2. Morphological and structural properties of the synthesized ZnO thin films

The SEM micrographs and the XRD spectra for a selected ZnO/Cu electrodes synthesized at 20 min electrodeposition time are shown in Fig. 3 and 4. It can be noted that, the morphology of the surface of ZnO deposited at -0.6 V (Fig.3 (a)) reveals the grains structure, with an inhomogeneous distribution. Increasing the potential at -0.8 V (Fig.3 (b)), the deposit becomes more compact, homogeneous and the surface is made from hexagonal shapes stems. For more cathodic potentials as -1V and -1.2V (Fig. 3(c and d)), the morphology of the ZnO modified electrode is in the form of flowers oriented on the substrates surface and each flower consists of petals. ZnO nanoflowers will offer large surface area and expected to enhance electrocatlytic activity.

The XRD measurements confirm the formation of ZnO thin films on Cu substrate (Fig. 4). Three pronounced peaks are observed in the as-prepared samples, which can be indexed to the (100), (002), and (101) reflections of ZnO at 2θ value of 31.7°, 34.4° and 36.3°, respectively. No other diffraction peaks were detected excluding the peaks originating from ZnO. Although all ZnO diffraction peaks are in good agreement with the JCPDS card (36-1451) for a wurtzite-type ZnO crystal. It can be seen that, for the ZnO thin film electrodeposited at -1V...
for 20 min, a significantly higher intensity of (002) diffraction peak is obtained indicating that ZnO flowers were preferentially oriented along the c-axis direction crystallographic face.

### 3.3. Electrochemical behavior of nitrate ions at bare Cu and ZnO/Cu modified electrode

In order to evaluate the electrocatalytic behavior of the ZnO/Cu modified electrode towards nitrate reduction, we performed voltammograms in absence of NO₃⁻ ions at Cu electrode (Fig.5 (a)) and in 0.01M KNO₃ at bare Cu (Fig.5 (b)) and at ZnO/Cu (Fig.5 (c)) electrodes.

It can be seen that, in the presence of NO₃⁻, a very broad reductive wave was observed on the voltammogram recorded at Cu bare electrode, corresponding to the reduction of nitrates, in agreement with the results of literature [16]. For the voltammogram recorded at the ZnO modified electrode obtained by chronoamperometry at -1V for 20 min, a one single, sharp and intense reduction peak appears at around -0.7 V/SCE (Fig.5(c)). This is the sign of increasing electrocatalytic activity on the ZnO/Cu modified electrode. Compared to the bare Cu electrode, in KNO₃ solution with a less intense peak reduction, we can conclude that the ZnO promoted the nitrates reduction. The increase in the peak current of the analytes at the surface of the ZnO/Cu (about 2.0 times) can be explained by the increase in electronic transfer due to the increase in the surface area or to the synergic effect between ZnO and Cu. Also, of one single, reduction peak is indicative a one steep reduction reaction. To -0.8 V the current intensity increases and this area corresponds to the reduction of proton.

### 3.4. Electrocatalytic reduction of nitrate onto ZnO/Cu modified electrode

It has already shown that the operating conditions have a directly effect on the morphology and properties of the deposits [24, 13].

In our study, we investigated the effects of electrodeposition time, bath temperature and deposition potential on the morphology and structure of the ZnO deposits and their possible effects on the electrocatalytic nitrate reduction.

#### 3.4.1. Effect of electrodeposition time and potential

Fig.6 (a, b, c and d) shows the effect of both electrodeposition potential and time on the electrocatalytic activity of ZnO/Cu towards nitrate reduction. Peak current of the CVs was increased with increasing electrodeposition time and potential, suggesting that the morphology and structure of the deposit have great influence on the electrocatalytic activity of ZnO/Cu modified electrodes towards nitrate reduction. It can be observed that, ZnO/Cu electrode obtained at 20 min electrodeposition time shows sharper reduction peak and higher current intensity for nitrate reduction for all potentials.

URL: http://mc.manuscriptcentral.com/tdwt
Figure 6 (e) summarizes the effects of potential on the electrocatalytic activity of ZnO/Cu electrode at 20 min electrodeposition time. These results indicated that the electrocatalytic action was more pronounced with the ZnO/Cu fabricated at -1 V. So these potential and time values were chosen as the optimums giving the best results. This increased electrocatalytic activity is probably due to the specific morphology shown by SEM analysis. In this case the ZnO deposit in the form of flowers is denser and covers the Cu substrate entirely leading to the increase in the surface area and improved mass transport. As electrodeposition time increases over 20 min the electrocatalytic nitrate reduction decreases probably due to the decrease of the synergetic effect between ZnO and Cu because Cu will be covered by more compact ZnO deposit. Also, the electrocatalytic nitrate reduction decreases for ZnO deposited at -1.2 V due to poor morphology and structure because of hydrogen competing reaction.

3.4.2. Effect of temperature

Fig. 7 shows the cyclic voltammetry of ZnO modified electrode deposited at -1 V for 20 min obtained at different temperatures. As can be seen from Fig. 7, an increase in the temperature results in an increase in the intensity of the peak of nitrate reduction. The increase in the intensity of the nitrate reduction corresponds to well-ordered ZnO deposit. This process can be explained by more efficient conversion of Zn (OH)2 to ZnO in an ultimate step due to the temperature effect. For the rest of our study we chose a temperature of 70°C to make deposits.

3.4.3. Effect of nitrate concentration

Fig. 8 shows the voltammograms of nitrate reduction in the concentration range of 0.03 - 10 mM KNO3 recorded using the ZnO/Cu electrode at a potential sweep rate of 8 mV s\(^{-1}\). We can see that the nitrate reduction peak current increases with increasing NO\(_3^-\) concentration and has a linear relationship with the concentration of NO\(_3^-\) in the considered range of concentration with a correlation coefficient of 0.9987. The regression equations is \(y=0.1374C_{NO3^-}+60.3676\) with \(R^2= 0.99815\). From these results, we can conclude that the ZnO/Cu electrode can be used for nitrate electroreduction and detection.

3.4.4. Chronoamperometric measurements on ZnO/Cu modified electrode in the presence of nitrate.

Figure 9 (a) illustrates the current versus time transients at a cathodic potential of -0.68 V/ SCE, onto ZnO/ Cu electrode in 10 mM of nitrate ions. This applied potential corresponds to the maximum peak for nitrate reduction (Fig.6.e). It is verified that, the variation of current \(i\) versus \(t^{1/2}\) is linear with a correlation coefficient of 0.9984 (Fig. 9(b)).
From the slope of the line $i = f \left( t^{-1/2} \right)$ (Fig.9 (b)) we can estimate the total number of electrons transferred during the reaction of nitrate reduction using the Cottrell equation (eq.1).

$$i = nFAD^{1/2}C_{NO_3}^{-1/2} \cdot \pi t^{-1/2}$$  \hspace{1cm} (eq.1)

where $C$ is the bulk concentration (mol. cm$^{-3}$), $D$ the diffusion coefficient, $n$ the number of electron transferred, $F$ the Faraday constant, $A$ the electrode area, $i$ is the current density controlled by the diffusion of NO$_3^-$ ions from the bulk solution to the electrode/solution interface.

To a concentration $C$ (NO$_3^-$) = 0.01M, $D = 2.10^{-5}$ cm$^2$.s$^{-1}$[5], $n$ is equal to 7.901 ($n = 8$) corresponding to the number of electrons exchanged in the reaction in accordance with nitrate reduction into ammonia (eq. 2).

$$NO_3^- + 9H^+ + 8e^- \rightarrow NH_3 + 3H_2O$$  \hspace{1cm} (eq.2)

The one step reduction reaction was indicative of rapid NO$_3^-$ reduction process occurring at the ZnO/Cu modified electrode. These results indicate that the reaction proceeds in one step and, might be used for ammonia synthesis, a useful product from the industrial point of view.

3.4.5. Effect of sweep rate

**Figure 10(a)** shows the CV responses of ZnO/Cu electrode at different scan rates (8, 20, 40, 60, 100 and 200 mV/s). We can see that the nitrate reduction current increases with the increase of sweep rate and was proportional to the square root sweep rate (Fig. 10(b)), implying that the reduction process is diffusion controlled.

**Conclusion**

The development of specific analytical methods for the detection and destruction of nitrate is of great importance to limit pollution of the natural environment.

In this study, the reduction of nitrate ions on copper electrodes modified by electrodeposition of ZnO thin films was investigated. The influence of both electrodeposition potential and time on the morphology and structure of ZnO was studied.

The obtained results showed that, these electrodeposition parameters have a great influence on the structure and morphology of the deposit. The structural analysis of ZnO obtained at -1 V versus SCE for 20min, by XRD shows a polycrystalline structure with a preferential
orientation along the c axis perpendicular to the substrate. SEM characterization shows a ZnO deposit in the form of flowers oriented on the substrate surface.

The results of the electrocatalytic study have shown that the copper electrode modified by ZnO thin films, at -1V for 20 min electrodeposition time exhibits excellent electrocatalytic activity towards the reduction of nitrate ions. The results are reproducible over a nitrate concentration range of [0.03 mM to 10 mM]. The number of electrons exchanged in the nitrate reduction reaction was determined by chronoamperometry study which is equal to 8. These results indicate that the reaction proceeds in one step and leads to ammonia a useful product from the industrial point of view. We can conclude that ZnO/Cu electrode might be used for ammonia synthesis as well as NO$_3^-$ detection.
