# How intramolecular hydrogen bonding (IHB) controls the C-ON bond homolysis in alkoxyamines $\dagger$ 

Gérard Audran, ${ }^{* a}$ Raphael Bikanga, ${ }^{\text {b }}$ Paul Brémond, ${ }^{\text {a }}$ Mariya Edeleva, (D) ${ }^{\text {c }}$ Jean-Patrick Joly, ${ }^{\text {a }}$ Sylvain R. A. Marque, (D) ${ }^{* a, c}$ Paulin Nkolo ${ }^{a}$ and Valérie Roubaud ${ }^{a}$

#### Abstract

Recent amazing results (Nkolo et al., Org. Biomol. Chem., 2017, 6167) on the effect of solvents and polarity on the $\mathrm{C}-\mathrm{ON}$ bond homolysis rate constants $k_{d}$ of alkoxyamine $\mathrm{R}_{1} \mathrm{R}_{2} \mathrm{NOR} R_{3}$ led us to re-investigate the antagonistic effect of intramolecular hydrogen-bonding (IHB) on $k_{d}$. Here, IHB is investigated both in the nitroxyl fragment $\mathrm{R}_{1} \mathrm{R}_{2} \mathrm{NO}$ and in the alkyl fragment $\mathrm{R}_{3}$, as well as between fragments, that is, the donating group on the alkyl fragment and the accepting group on the nitroxyl fragment, and conversely. It appears that IHB between fragments (inter $\mathrm{H} H \mathrm{~B}$ ) strikingly decreases the homolysis rate constant $k_{d}$, whereas IHB within the fragment (intra IHB) moderately increases $k_{d}$. For one alkoxyamine, the simultaneous occurrence of IHB within the nitroxyl fragment and between fragments is reported. The protonation effect is weaker in the presence than in the absence of IHB. A moderate solvent effect is also observed.

## Introduction

Since the pioneering work of Rizzardo and co-workers, ${ }^{1,2}$ alkoxyamines have been applied in several fields such as tinfree radical organic chemistry ${ }^{3,4}$ - as initiators for radical cyclization, ${ }^{5,6} 1,2$-radical additions, ${ }^{7}$ and several others ${ }^{5}$ - NMP (nitroxide mediated polymerization) and its variants: in situ NMP, ${ }^{8}$ ESCP, ${ }^{9}$ NMP2, ${ }^{10,11}$ SL-NMP, ${ }^{12}$ and CI-NMP, ${ }^{13}$ materials sciences - for self-healing polymers, ${ }^{14}$ optoelectronic materials, ${ }^{15}$ and encoding systems ${ }^{16}$ - and in biology, ${ }^{17-19}$ as agents for theranostics. For alkoxyamines to be used as agents for theranostics (Fig. 1), the concept of a "smart" alkoxyamine was proposed, ${ }^{17}$ that is, a highly stable alkoxyamine switching to a highly labile alkoxyamine through chemical reactions (Fig. 2). For several years, our group has been promoting the chemical alkoxyamine activation using protonation, ${ }^{20}$ oxi-

[^0]

dation,,$^{20}$ alkylation, ${ }^{20}$ or metal cation coordination. ${ }^{21,22}$ However, in our view, activation processes based on physicochemical events cannot be disregarded. Indeed, very recently, ${ }^{23}$ a dramatic solvent effect on the $\mathrm{C}-\mathrm{ON}$ bond homolysis rate constant $k_{\mathrm{d}}$ (Scheme 1) has been reported for 1 (Fig. 3). Intramolecular hydrogen-bonding (IHB) displays very different trends, that is, IHB within the nitroxyl fragment affords an

Scheme 1 C-ON bond homolysis in alkoxyamines.
increase in $k_{\mathrm{d}}$ (Fig. 4a) ${ }^{24-27}$ and IHB from the alkyl fragment to the nitroxyl fragment (interR, Fig. 4c) affords a decrease in $k_{\mathrm{d}}$ spanning from weak $\left(2-3 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)^{28}$ to moderate ${ }^{29}$ (ca. $10 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ). Interestingly, other types of IHBs have not yet been investigated - IHB from the nitroxyl fragment to the alkyl fragment (interN, Fig. 4d) and IHB within the alkyl fragment (Fig. 4b) - and are the focus of this article. Several models 2-7 (Fig. 3) were prepared and their structures were determined by X-ray and NMR analysis.

The occurrence and the type of IHB were determined by combining ${ }^{31} \mathrm{P}$ and ${ }^{1} \mathrm{H}$ NMR with DFT calculations. The influ-

ence of IHB on $k_{\mathrm{d}}$ was investigated in tert-butylbenzene ( $t$-BuPh) as a non-polar solvent and water as a polar/hydrogen bond acceptor (HBA) solvent, known to suppress IHB. ${ }^{30}$

## Results

## Preparation of alkoxyamines 2-7

Alkoxyamine 3 was prepared either as previously reported ${ }^{26}$ (black route in Scheme 2) or by the hydrolysis ${ }^{31}$ of 2 prepared from protected amino alcohol 2a (blue and magenta routes in Scheme 2). Alkoxyamine 2 was prepared either by the protection $^{32}$ of 3 (black route in Scheme 2) or from the protected phosphorylated amino alcohol 2b (magenta route in Scheme 2).

Alkoxyamine 4 was prepared using the conventional Mn (salen) ${ }_{2}$ salt procedure (Scheme 3). ${ }^{33}$ The two diastereoisomers

Scheme 2 Preparation of 2 and 3: (a) (1) 2a or 3a (1.1 eq.), t-Bu-CHO (1 eq.), pentane, $65^{\circ} \mathrm{C}, 2$ day, (2) (EtO) $2 \mathrm{P}(\mathrm{O}) \mathrm{H}$ (1.1 eq.), $45^{\circ} \mathrm{C}, 7$ days, $64-78 \%$; (b) 2 b or 3 b (1 eq.), Oxone® ( 4 eq.), $\mathrm{Na}_{2} \mathrm{CO}_{3}$ ( 6 eq.), EtOH/ $\mathrm{H}_{2} \mathrm{O}$ (3:1), $5 \mathrm{~h}, \mathrm{rt}, 51-56 \%$; (c) (1) $\mathrm{Cu}(0)$ ( 1.1 eq.$), \mathrm{CuBr}$ ( 0.55 eq.$), ~ P M D E T A$ ( 0.55 eq.), argon bubbled benzene, 30 min , rt , (2) 1-bromoethylbenzene ( 1.1 eq .), $2^{\circ}$ or $3^{\circ}$ ( 1 eq .), rt, overnight, $65-72 \%$; (d) $3 \mathrm{a}, 3 \mathrm{~b}$, or 3 (1 eq.), $t$ - $\mathrm{BuMe}_{2} \mathrm{SiOTf}$ ( 1.5 eq.), 2,6-lutidine ( 2 eq.), DCM, $4 \mathrm{~h}, \mathrm{rt} 80-90 \%$; (e) 2 (1 eq.) TBAF (1 M in THF) (1.2 eq.), THF, rt, 92\%.

Scheme 3 Preparation of 4 and 5: (a) (1) salen ligand ( 0.05 eq.), $\mathrm{MnCl}_{2}$ ( 0.05 eq.), i-PrOH, $30 \mathrm{~min}, ~ r t ; ~(2) 3^{\circ}(1 \mathrm{eq}$. ), 2 -vinyl pyridine (1 eq.), i-PrOH; (3) $\mathrm{NaBH}_{4}$ (5 eq.), 4 h, rt, 54\%; (b) (1) 4 (1eq.), pyridine (5 eq.), $\mathrm{AgNO}_{3}$ (1.5 eq.), THF, $5 \mathrm{~min}, \mathrm{rt}$; (2) $t-\mathrm{BuMe} \mathrm{C}_{2} \mathrm{SiCl}$ (1.5 eq.), overnight, rt, 59-67\%.
were separated and $R R / S S-4 \ddagger$ was recrystallized. Then, it was protected using $t$ - $\mathrm{BuMe}_{2} \mathrm{SiCl}$ to afford 5 in good yield (Scheme 3). ${ }^{34} \S$

Alkoxyamine 6 was prepared from the corresponding bromide $\mathbf{6 b}$ coupled to $\mathbf{6}^{\circ}$ using the conventional ATRA procedure. ${ }^{35}$ However, 7 was obtained as a crude mixture of diastereoisomers which cannot be separated. Then, crude 7 was hydrolyzed into crude 6 whose diastereoisomers were separated, and the diastereoisomer $R S / S R \ddagger$ was crystallized. The diastereoisomers of 6 were acetylated into 7 (Scheme 4).

## X-ray analysis

Alkoxyamines $R R / S S-4$ and $R S / S R-6$ were crystallized and analyzed by XRD (Fig. 5). $\ddagger$ X-ray structures exhibit the conventional distances and angles observed for such types of molecules (see the ESI $\dagger$ ). Dihedral angles $\left\langle\mathrm{O}_{5} \mathrm{C}_{6} \mathrm{C}_{7} \mathrm{~N}_{8}\right\rangle$ are $45^{\circ}$ and $90^{\circ}$ larger (Fig. 6d) than the $90^{\circ}$ required at TS for $R R / S S-4$ and $R S /$ $S R-6$, respectively. ${ }^{36}$ However, from the X-ray structure (Fig. 5 and 6) it is clear that no IHB occurs in $R R / S S-4$ in the solid state although it is a good model to observe IHB of type (a) or (d) (Fig. 4) or both. By contrast, $R S / S R-6$, which is a good model for IHB of type (b) or (c) or both (Fig. 4), exhibits only IHB of type (c). $\cdot \|^{37,38}$ The absence of IHB in the $R R / S S$-4 X-ray

Scheme 4 Preparation of 6 and 7: (a) 5a (1 eq.), NBS (1.1 eq.), benzoyl peroxide ( 0.1 eq.), $\mathrm{CCl}_{4}$, reflux, $69 \%$; (b) (1) CuBr ( 0.5 eq ), $\mathrm{Cu}(0)$ (1 eq.), PMEDTA ( 0.5 eq.), benzene, Ar, $10 \mathrm{~min}, \mathrm{rt}$; (2) $6^{\circ}$ ( 1.1 eq ), 6 b (1 eq.), benzene, 12 h , rt, (3) $\mathrm{MeOH}, \mathrm{K}_{2} \mathrm{CO}_{3}, \mathrm{H}_{2} \mathrm{O}, 3$ days, $\mathrm{rt}, 63 \%$; (c) (1) 6 (1 eq.), $\mathrm{Et}_{3} \mathrm{~N}$ (4 eq.), $\mathrm{CH}_{2} \mathrm{Cl}_{2}$; (2) $\mathrm{Ac}_{2} \mathrm{O}$ (3 eq.), 3 days, rt, 65-90\%.

Fig. 5 X-ray structures for $R R / S S-4$ (left) and $R S / S R-6$ (right). $\ddagger$
structure is in sharp contrast with its occurrence in solution (vide infra). This difference in conformation between the crystal and solution has already been observed several times for alkoxyamines ${ }^{27,28}$ and it is ascribed to the packing effect, which forces intermolecular H-bonding at the expense of IHB.

## NMR analysis

In contrast with XRD, ${ }^{1} \mathrm{H}$ and ${ }^{31} \mathrm{P}$ NMR spectra show that IHBs of types (a) and (d) occur at the same time for $R R / S S-4$. $\|$ As already reported for 2 and $3,{ }^{29} \Delta \delta$ for 4 and 5 decreases from benzene- $d_{6}$ to DMSO- $d_{6}$ (Table 1 and Fig. 7), as expected from the increase in the parameter $\beta^{30}$ - the hydrogen bond acceptor (HBA) property of the solvent - that is, the increase in the ability to suppress IHB. The occurrence of IHB between the diethylphosphoryl and the hydroxyl groups (intraN in Fig. 8) is supported by the difference in shifts $\delta$ and the signal pattern for the $\mathrm{MeCH}_{2} \mathrm{O}$ group observed between $R R / S S-4$ and $R R / S S-5$ in benzene- $d_{6}$ (protons labelled a in Fig. 9)** and its suppression in DMSO- $d_{6}$ (very similar patterns for protons labelled a-c for $R R / S S-4$ and $R R / S S-5$ in Fig. 9). However, the chemical shifts $\delta$ and the signal pattern of pyridyl protons (Fig. 9) are very different for $R R / S S-4$ and $R R / S S-5$ in benzene- $d_{6}$, while they are similar in DMSO- $d_{6}$. As similar observations were also reported upon protonation (or other types of activation) of the pyridyl moiety in alkoxyamines, ${ }^{20-22}$ this change in the signal is ascribed to the occurrence of IHB between the hydroxyl group and the pyridyl moiety (interN in Fig. 8). Temperature

- $d_{\mathrm{P}=\mathrm{O} \cdots \mathrm{HO}}=1.96 \AA$ and $<\mathrm{O}_{1} \mathrm{H}_{15} \mathrm{O}_{14}>=164^{\circ}$. The bond radii of $\mathrm{H}, \mathrm{N}$ and O are $r_{\mathrm{H}}=1.09 \AA, r_{\mathrm{N}}=1.55 \AA$ and $r_{\mathrm{O}}=1.52 \AA$, respectively. See ref. 37.
$\| R R / S S$ - 5 exhibiting no IHB was chosen as a model for $\mathbf{4}$ and very similar solvent effects were expected.
** Protons from $\mathrm{CH}_{2} \mathrm{OH}$ (labelled e in Fig. 9) are expected to be sensitive to the silylation of the hydroxyl functions, whereas protons labelled $b$ and $c$ are not expected to be very sensitive.

${ }^{a} 85 \% \mathrm{H}_{3} \mathrm{PO}_{4}$ was used as an internal reference ( 0 ppm ). ${ }^{b}$ Hydrogen bond acceptor parameter $\beta$. Given in ref. 30. ${ }^{c}$ Ratio $\mathbf{4 : 5}=2: 1 .{ }^{d} \Delta \delta=$ $\delta_{4}-\delta_{5}$.

Fig. $7{ }^{31} \mathrm{P}$ NMR signals in various solvents for (a) a (2:1) mixture of $R R /$ SS-4 (left) and RR/SS-5 (right), and (b) a (2:1) mixture of RS/SR-4 (left) and $R S / S R-5$ (right).

Fig. 8 Possible conformations affording intraN IHB (left), interN IHB (middle), and 3-center IHB (right) for RR/SS-4.

Fig. $9 \quad{ }^{1} \mathrm{H}$ NMR spectra of $R R / S S-4$ (top) and $R R / S S-5$ (bottom) in the range $2.5-6 \mathrm{ppm}$ (top row) and $6-9 \mathrm{ppm}$ (pyridyl proton zone, bottom row) in benzene- $d_{6}$ (left) and DMSO- $d_{6}$ (right). Labelling of protons: a-e represent $\mathrm{MeCH}_{2} \mathrm{O}, \mathrm{CHP}, \mathrm{CHMe}, \mathrm{OH}$, and $\mathrm{CH}_{2} \mathrm{O}$, respectively.
dependence shows only line broadening when the temperature is decreased down to $-80{ }^{\circ} \mathrm{C}$, meaning that the rotation around the $\mathrm{C}-\mathrm{N}$ bond of the group carrying the hydroxyl function is faster than the resolution time of ${ }^{1} \mathrm{H}$ NMR. DFT calculations (vide infra) led us to disregard the occurrence of 3-center IHB, as shown in Fig. 8.

The same trends are observed for $\Delta \delta$ (Fig. 7 and Table 1) and ${ }^{1} \mathrm{H}$ NMR signals of EtO protons (labelled a in Fig. 1SI $\dagger$ ) for $R S / S R$ diastereoisomers of $\mathbf{4}$ and 5 as those for diastereoisomers $R R / S S$ and are ascribed to the occurrence of IHB between the diethylphosphoryl and the hydroxyl groups (Fig. 10). In sharp contrast to what was observed for the diastereoisomer $R R / S S$, no significant differences in chemical shifts and signal patterns in the pyridyl proton zone are observed for $R S / S R-\mathbf{4}$ and $R S / S R-\mathbf{5}$, whatever the solvent (Fig. 1SI $\dagger$ ). Consequently, only intraN IHB (type (a) in Fig. 4) is observed in $R S / S R$-4 (Fig. 10a).

The same trends are observed for $\Delta \delta$ (Fig. 11b and Table 2) and ${ }^{1} \mathrm{H}$ NMR signals of EtO protons (labelled a in Fig. $2 \mathrm{SI} \dagger$ ) for $R S / S R$ diastereoisomers of 6 and 7 as those for 4 and 5 (vide

${ }^{a} 85 \% \mathrm{H}_{3} \mathrm{PO}_{4}$ was used as an internal reference ( 0 ppm ). ${ }^{b}$ Hydrogen bond acceptor parameter $\beta$. Given in ref. 30. ${ }^{c}$ Ratio 6:7 $=2: 1 .{ }^{d} \Delta \delta=$ $\delta_{6}-\delta_{7}$.
supra) and are ascribed to the occurrence of IHB between the diethylphosphoryl and the hydroxyl groups (Fig. 6) in RS/SR-6. On the other hand, the very similar signal patterns of protons in the aromatic zone for $R S / S R-6$ and $R S / S R-7$ (Fig. 2SI $\dagger$ ) support the non-occurrence of intraR IHB (type b in Fig. 4 and 6).

No significant changes in $\Delta \delta$ (Table 2 and Fig. 11b) and in the signal patterns of EtO-groups (protons labelled a in Fig. $3 \mathrm{SI} \dagger$ ) are observed for $R R / S S-6$ and $R R / S S-7$, pointing to the absence of interR IHB (type c in Fig. 4). By contrast, significant

Fig. $12{ }^{1} \mathrm{H}$ NMR spectra of $R R / S S-6$ (top) and RR/SS-7 (bottom) in the range $3-6 \mathrm{ppm}$ (top row) and $6-9 \mathrm{ppm}$ (pyridyl proton zone, bottom row) in $\mathrm{CDCl}_{3}$ (left) and DMSO- $d_{6}$ (right). Labelling of protons: a-e represent $\mathrm{MeCH}_{2} \mathrm{O}, \mathrm{CHP}, \mathrm{CHMe}, \mathrm{OH}$, and $\mathrm{CH}_{2} \mathrm{O}$, respectively.
changes in the signal patterns of aromatics are observed between $R R / S S$ - 6 and $R R / S S$ - 7 in benzene- $d_{6}$, whereas very similar signal patterns for $R S / S R-6$ and $R S / S R-7$ are observed (Fig. 12) in DMSO- $d_{6}$, i.e., the absence of any type of IHB, supporting the occurrence of intraR IHB in $R R / S S$ - 6 in benzene- $d_{6}$ (Fig. 10b).

## Protonation of alkoxyamines

Alkoxyamines 4-7 carry a pyridyl moiety on the alkyl fragment suitable for activation by protonation. Consequently, protonation in benzene- $d_{6}$ (model for tert-butylbenzene $t$-BuPh) in the presence of trifluoroacetic acid is confirmed by changes in ${ }^{1} \mathrm{H}$ NMR shifts in the aromatic zone, e.g. $R R / S S-4$ (Fig. $4 S I \dagger$ ). The values of $\mathrm{p} K_{\mathrm{a}}(\text { Table } 3)^{39}$ are estimated from the ${ }^{1} \mathrm{H}$ NMR shift of the signal in the aromatic zone, e.g., $R R / S S-4$ (Fig. 13), and are given by the modified Hasselbach-Henderson equation (eqn (1), exemplified by $\mathbf{4} / \mathbf{4} \mathbf{H}+$, and Table 3). ${ }^{40,41}$

$$
\begin{equation*}
\delta_{\mathrm{pH}}=\delta_{4}+\frac{\delta_{4 \mathrm{H}+}-\delta_{4}}{1+10^{\mathrm{p} K_{\mathrm{a}}-\mathrm{pH}}} \tag{1}
\end{equation*}
$$

As already reported, the $\mathrm{p} K_{\mathrm{a}}$ of $\mathbf{1 2}$ is $c a .1 .7-1.9$ units lower than that reported for the ortho-ethylpyridine. It is ascribed to the presence of the nitroxyl fragment as a strong electron withdrawing group (EWG). The one unit lower $\mathrm{p} K_{\mathrm{a}}$ for the orthohydroxyethylpyridine is also ascribed to the presence of the OH group as an EWG. Therefore, the lower $\mathrm{p} K_{\mathrm{a}}$ values for 4-7 (Fig. 13) than those for ortho-ethylpyridine and ortho-hydroxyethylpyridine are due to the presence of the nitroxyl fragment as an EWG. It is noteworthy that alkoxyamines 4-6 exhibit $\mathrm{p} K_{\mathrm{a}}$ values very close to those for model $\mathbf{1 2}$, except for $R R / S S-6$.

The one unit lower $\mathrm{p} K_{\mathrm{a}}$ value for 7 than that for 12 is ascribed to the acylated hydroxyl group, which exhibits a higher electron withdrawing property than the OH group, the basicity of the pyridine moiety being thus decreased.

## Kinetic investigations

Homolysis rate constants $k_{\mathrm{d}, \mathrm{T}}$ were measured using either the ${ }^{31} \mathrm{P}$ NMR method ${ }^{27}$ for $\mathbf{4}, \mathbf{4} \mathbf{H}+, 5,7$ and $7 \mathbf{H}+$ or the EPR method $^{20}$ for $2,2^{\prime}, 2^{\prime \prime}, 3^{\prime}, 6$ and $\mathbf{6 H}+$, as previously reported. Differences in $E_{\mathrm{a}}$ observed between diastereoisomers for 2, $\mathbf{2}^{\prime}$, $2^{\prime \prime}, 3,5$ and 7 in $t$-BuPh as a solvent are in the range of

See the ESI. ${ }^{d} \mathrm{p} K_{\mathrm{a}}$ values of $4.21(R S / S R)$ and $3.99(R R / S S)$ were reported for 12 . See ref. 41.

Fig. 13 Titration curves for $R R / S S-4(0.01 \mathrm{M}$, ■, inset: signal of the aromatic proton zone) and $R S / S R-4(0.01 \mathrm{M}, \bullet), \mathrm{D}_{2} \mathrm{O} / \mathrm{MeOH}-d_{4}=1: 1$.
$0-2 \mathrm{~kJ} \mathrm{~mol}{ }^{-1}$ - generally observed for diastereoisomers reported in the literature - and do not deserve more comments. ${ }^{36}$ Alkoxyamines exhibiting IHB are discussed later. Except for 6, comments made for diastereoisomers in $t$-BuPh as a solvent hold in water, as IHB is suppressed.

## DFT calculations

DFT calculations at the M062X/6-31+G(d,p) level of theory in the gas phase were performed to determine both the thermodynamics of the homolysis and the most stable conformations for the diastereoisomers of 2-4 and $\mathbf{6}$ (Table 1SI $\dagger$ ). ${ }^{42}$ Important geometrical parameters - bond lengths, distances and angles are reported in Table 1SI $\dagger$ and agree with X-ray data and those reported for molecules of the same family, except for the occurrence of IHB in $R R / S S-4$. Thermodynamics of 4 and 6 show the same trends as that experimentally reported (Table $1 \mathrm{SI} \dagger$ ). Only the 3 most stable conformations A, B and $\mathrm{C} \dagger \dagger$ are reported for 4 and 6 (Fig. 14). Valence angles, bond lengths and distances for IHB are reported in Table 5. Depending both on the valence angle $\alpha$ and on the distance $d_{\mathrm{H} \cdots \mathrm{x}}$ between the H and X atoms implied in the H -bonding, IHB is given as strong $\left(\alpha>150^{\circ}\right.$ and $d$ smaller than the sum of van der Waals radii of H and X atoms), as weak ( $\alpha<120^{\circ}$ and $d$ closer to the sum of the van der Waals radii of H and X atoms) or as medium for other combinations. $\|^{37,38}$ On these grounds, IHB for the most stable conformers is considered as strong for $R S / S R-\mathbf{6}$ (conformer A) and $R S / S R-\mathbf{9}$, and as medium for other diastereoisomers (Fig. 14 and Table 5). For all cases, IHB is smaller by $c a .1 .8 \AA$ and by $0.5 \AA$ for $\mathrm{OH} \cdots \mathrm{O}=\mathrm{P}$ and for $\mathrm{OH} \cdots \mathrm{N}$ interactions, respectively, than the respective sums of van der

[^2]Waals radii $-d_{\mathrm{OH} \cdots \mathrm{OP}}=2.61 \AA$ and $d_{\mathrm{OH} \cdots \mathrm{N}}=2.64 \AA-$ and all valence angles $\alpha$ are larger than $130^{\circ}$. Nevertheless, the occurrence of IHB is controlled mainly by the steric hindrance. As illustrated by $R R / S S-9$, when steric hindrance is too large, IHB does not occur, and in some cases, for example, $R R / S S-4$ and $R R / S S$-6, the most stable conformer B does not display the strongest IHB. $+\ddagger$ All other possible IHBs are disregarded due to distances $d_{\mathrm{OH} \cdots \mathrm{OP}}$ and $d_{\mathrm{OH} \cdots \mathrm{N}}$ much larger than the sums of the van der Waals radii, except for $\mathrm{OH} \cdots \mathrm{NO}$ for the conformer C of $R S / S R-6$. Nonetheless, the IHB observed between the hydroxyl group and the N atom of the nitroxyl moiety in the conformer $\mathbf{C}$ is not strong enough to balance the steric strain in $\mathbf{C}$, which is less stable than $\mathbf{A}$ by $19 \mathrm{~kJ} \mathrm{~mol}^{-1}$ (Fig. 14).

## Discussion

## Free motions in the nitroxyl fragment

Taking into account (i) NMR observations for $R R / S S$ - 4 denoting the simultaneous occurrence of intraN and interN IHBs (Fig. 4), (ii) calculations ascribing these two IHBs to two different conformers (Fig. 14 and Table 5), (iii) dramatically restricted bond rotations in the group carrying the diethylphosphoryl group attached to the nitroxyl moiety in nitroxides, and in the subsequent alkoxyamines, $\S \S^{43-45}$ the question of the free rotation around the $\mathrm{C}-\mathrm{N}$ bond for the other alkyl group attached to the nitroxyl moiety is raised. Indeed, the conformations of the nitroxyl fragment are expected to be ruled by the conformations of the nitroxide, as highlighted by the occurrence of the same IHB in $3^{\cdot 26}$ and $3 .^{27}$ Whatever the route for the preparation of 2 and 3 (Scheme 2 and ESI $\dagger$ ), ${ }^{1} \mathrm{H}$ NMR spectra of intermediates are the same (see the ESI $\dagger$ ) as well as $k_{\mathrm{d}}$ values within the experimental error (Table 4), supporting that for the group carrying the hydroxyl function, the rotation of the $\mathrm{C}-\mathrm{N}$ bond is free, whereas the rotation of the $\mathrm{C}-\mathrm{N}$ bond for the moiety carrying the diethylphosphoryl group

[^3]

Fig. 14 Most stable conformations $\mathrm{A}-\mathrm{C} \dagger \dagger$ for $R R / S S-4, R S / S R-4, R R / S S-6$, and $R S / S R-6$. All conformers are on the same energetic scale ( kJ mol ${ }^{-1}$ ). Dotted lines for the difference in energy between isomers and full lines for the difference in energy between conformers.

is, in general, strongly restricted in the nitroxide, ${ }^{46,47}$ and likely in the alkoxyamine.

## IHB in alkoxyamines

A quick glance at $\mathbf{3}, \mathbf{4}, 6$ and 9 shows that several types of IHBs may occur (Fig. 4). The occurrence of inter IHB for $R S / S R-9$ has been reported in the literature. ${ }^{29}$ It has been observed by X-ray, ${ }^{29} \mathrm{NMR},{ }^{29}$ and $\mathrm{IR}^{29}$ and is supported by DFT calculations and does not deserve more comments, as $R S / S R-9$ is used as a model. Diastereoisomer $R R / S S-9$ does not exhibit IHB. ${ }^{29}$ The occurrence of intraN IHB for 3 was recently studied by NMR $\mathbb{T | T |}{ }^{27}$ and supported by DFT calculations in this work (see the ESI $\dagger$ and Table 5) and does not deserve more comments. X-ray data, NMR analysis, and DFT calculations support IHB of type interR, intraR, and intraN (Fig. 4, 8, 10 and 14) for $R S / S R-6$, $R R / S S-6$, and $R S / S R-4$, respectively (see the ESI $\dagger$ ). In contrast with diastereoisomer $R S / S R-6$, no IHB is observed in diastereoisomer $R R / S S$-4 by X-ray analysis, although ${ }^{31} \mathrm{P}$ NMR supports the occurrence of intraN IHB, ${ }^{1} \mathrm{H}$ NMR supports the occurrence of interN IHB. The appealing 3-center IHB displayed in Fig. 8 is disregarded by DFT calculations (too high energy conformer).|||| On the other hand, DFT calculations show a small difference in energy of $2.5 \mathrm{~kJ} \mathrm{~mol}^{-1}$ between the stable conformer $\mathbf{B}$ and conformer A, more stable than $\mathbf{C}$ by $16 \mathrm{~kJ} \mathrm{~mol}^{-1}$, meaning that a fast equilibrium between $\mathbf{B}$ and $\mathbf{A}$ likely

[^4]accounts for the simultaneous occurrence of intraN and interN IHBs observed by NMR. This fast equilibrium requires fast bond rotation around the $\mathrm{C}-\mathrm{N}$ bond of the group carrying the hydroxy function. This fast rotation is nicely supported both by the temperature dependence of $R R / S S-4$ (not shown) and the kinetics and NMR observations reported for 2 and 3 (vide supra). The small difference in energy of $8 \mathrm{~kJ} \mathrm{~mol}^{-1}$ between diastereoisomers of $\mathbf{4}$ agrees with the small difference of $1.6 \mathrm{~kJ} \mathrm{~mol}^{-1}$ in $E_{\mathrm{a}}$.

## Influence of IHB on $\boldsymbol{k}_{\mathrm{d}}$

Several linear multiparameter relationships developed over the last two decades to investigate various effects involved in the changes in $k_{\mathrm{d}}{ }^{25,36}$ cannot account for the effect of IHB. In parallel with these relationships, the group additivity approach ${ }^{48}$ provides $E_{\mathrm{a}}$ values predicted with a good accuracy using a scale developed a decade ago. ${ }^{49}$ To use the group additivity approach, alkoxyamine $\mathbf{1 1}$ was selected as a benchmark, as it displays the nitroxyl fragment with the lowest functionalization in that series and a secondary aromatic alkyl fragment. Thus, estimated activation energies $E^{\prime}$ a were determined (Table 4 and ESI $\dagger$ ). Taking into account the small difference in polarity between the alkyl fragment carrying a pyridyl $\left(\sigma_{\mathrm{I}}=0.06\right)^{50,51}$ or a phenyl $\left(\sigma_{\mathrm{I}}=0.07\right)^{52}$ moiety, no significant difference was reported, ${ }^{41}$ and the presence of the hydroxyl group capable of intraR IHB does not provide more than a 2 -fold increase in $k_{\mathrm{d}}$, as highlighted by the couples $\mathbf{6 / 9}$ and $\mathbf{4 / 3}$. To unveil the effect of IHB on $k_{\mathrm{d}}$, the hydroxyl group was protected by silylation in 2 and 5 , by methylation in 8 , and by acylation in 7 and $\mathbf{1 0}$, to suppress the occurrence of IHB (see the ESI $\dagger$ ). Kinetic results

Fig. 15 A 3D plot highlighting the relationship between the energetic effect of IHB $\Delta_{\text {IHB }}\left(\mathrm{kJ} \mathrm{mol}^{-1}\right)$, IHB valence angle $\alpha\left({ }^{\circ}\right)$, IHB distances $d_{\mathrm{OH} \ldots \mathrm{x}}$ ( A ) for the diastereoisomers of $3,4,6$ and 9 . Black and red symbols are intra and inter fragment IHB, respectively (see Fig. 4). Blue dots are for projection on the $X Y$ plane.
showed that the 4 types of IHBs can be gathered into two main families: alkyl and nitroxyl fragments exhibiting intra IHB which show no significant differences (less than a factor 2) between the alkoxyamines carrying the free hydroxyl group (3, $R S / S R-4$, and $R R / S S-6$ ) and those carrying the protected hydroxyl group (2, $R S / S R-5$, and $R R / S S-7$ ) and inter IHB between alkyl and nitroxyl fragments which shows a clear 6-9fold decrease in $k_{\mathrm{d}}$ between the alkoxyamines carrying the free hydroxyl group (diastereoisomers $R S / S R$ of 6 and 9) and those carrying the protected hydroxyl group (diastereoisomers $R S / S R$ of 7 and 10). Deeper insights into the geometrical parameters - the IHB valence angle $\alpha<\mathrm{OHX}>$ and the IHB distance $d_{\mathrm{OH} \cdots \mathrm{x}}$ - ruling the strength of the IHB and its influence on $k_{\mathrm{d}}$ given by $\Delta_{\text {IHB }}$ (see Table 5 ) are unveiled by the 3 D plot $f\left(\Delta_{\mathrm{IHB}}, d, \alpha\right)$ in Fig. 15. Indeed, intra IHB exhibits a very weak effect $\left(-1<\Delta_{\text {IHB }}\right.$ $<0 \mathrm{~kJ} \mathrm{~mol}^{-1}$ except for intraN in $R R / S S-4$ ) associated with short H-bonds $\left(d_{\mathrm{OH} \cdots \mathrm{x}}<1.9 \AA\right)$ and closed angles $\alpha\left(\alpha<150^{\circ}\right)$ denoting medium strength IHB, ${ }^{* * *}$ whereas interR IHB exhibits a strong effect $\left(\Delta_{\mathrm{IHB}}>6 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)$ associated with short H-bonds $\left(d_{\mathrm{OH} \cdots \mathrm{x}} \approx 1.8 \AA\right)$ and open angles $\alpha\left(\alpha \approx 175^{\circ}\right)$ denoting strong IHB. As mentioned above, diastereoisomer $R R / S S-4$ simultaneously displays intraN and interN IHBs and, thus, the decay of $R R / S S-4$ is described in Scheme 5 with $K_{1}=k_{1} / k_{-1}$ for the equilibrium constant between inter $N$ and intraN conformers, and $k_{2}$ and $k_{3}$ the rate constants for the homolysis of inter $N$ and intraN conformers, respectively. Taking into account that interN IHB makes a bond between nitroxyl and alkyl fragments as interR IHB does, the same effect is expected, i.e., an increase in $E_{\mathrm{a}}$ in regard to the homologue with no IHB. Therefore, $k_{3}$

[^5]$$
3 \cdot+\mathbf{R} \cdot \stackrel{k_{3}}{\leftarrow} \text { inter } N \stackrel{k_{1}}{k_{-1}} \text { intraN } \xrightarrow{k_{2}} 3 \cdot+\mathbf{R} \cdot
$$

Scheme 5 Equilibrium between interN and intraN IHB and the subsequent homolysis.
must be smaller than $k_{2}$ which corresponds to intraN IHB noted to increase $k_{\mathrm{d}}$ (vide supra). Hence, disregarding $k_{3}$, and assuming both a fast equilibrium - supported by very close calculated energy levels (vide supra) - between conformers B (interN) and $\mathbf{A}$ (intraN) and the pre-equilibrium assumption ( $k_{-1} \ggg k_{2}$ and $K_{1}=k_{1} / k_{-1}$ ), $k_{\mathrm{d}}$ (considered as the apparent rate) is given as $k_{\mathrm{d}}=k_{1} k_{2} /\left(k_{-1}+k_{2}\right)$ (eqn (2) or as $k_{\mathrm{d}}=K_{1} k_{2}$ as in eqn (3), Scheme 5). As the decrease in $E_{\mathrm{a}}$ is in the expected range (see Table 4), the values of $k_{\mathrm{d}}$ should be very close to $k_{2}$, meaning that $K_{1} \approx 1$ is in good agreement with the value estimated by DFT calculations, i.e., $K_{1}=0.42 . \dagger \dagger \dagger$

$$
\begin{gather*}
\frac{\mathrm{d}\left[3^{\bullet}\right]}{\mathrm{d} t}=\frac{k_{1} k_{2}}{k_{-1}+k_{2}}[\text { inter } N]  \tag{2}\\
\frac{\mathrm{d}\left[\mathbf{3}^{*}\right]}{\mathrm{d} t}=K_{1} k_{2} \cdot[\text { inter } N] \tag{3}
\end{gather*}
$$

## Solvent effect on $\boldsymbol{k}_{\mathrm{d}}$

The solvent effect in alkoxyamines does not increase too much interest despite the very amazing results recently reported, such as a striking 1500 -fold increase in $k_{\mathrm{d}}$ from $t$-BuPh to water as solvents or a slight but clear 5 - 20 -fold increase in $k_{\mathrm{d}}$ for homologue alkoxyamines of $\mathbf{1 2} .{ }^{53,54}$ Solvent effects for $3,{ }^{27}$ $\mathbf{9},{ }^{29}$ and $12{ }^{41}$ have been previously reported. Alkoxyamines 4, 6, 9 and 12 show a small $c a$. 1.5-3-fold increase in $k_{\mathrm{d}}$, as expected from the literature, ${ }^{53,54}$ except for $R S / S R-\mathbf{4}, R S / S R-6$ and $R S / S R-9$. The 3 -fold and 5 -fold increases in $k_{\mathrm{d}}$ for diastereoisomers $R S / S R$ of $\mathbf{6}$ and 9 are ascribed to the suppression of IHB from $t$-BuPh to water/MeOH as solvents. The slight 4.5fold increase in $k_{\mathrm{d}}$ observed for $R S / S R-4$, from $t$-BuPh to water/ MeOH as solvents, might be ascribed to the suppression of stabilizing IHB which balances the steric strain due to the configuration. The unexpected slight ca. 2-fold decrease in $k_{\mathrm{d}}$ for 3 is ascribed to a better solvation of the alkoxyamine, and hence a better stabilization, and higher $E_{\mathrm{a}}$ from $t$ - BuPh to water $/ \mathrm{MeOH}$ as solvents than for the other alkoxyamines investigated.

For protonated alkoxyamines $\mathbf{4 H}+\mathbf{6 H}+$ and $\mathbf{1 2 H} \mathbf{+}$, a 3-12fold increase in $k_{\mathrm{d}}$ is observed and is ascribed to intimate ion pair dissociation and solvation effects, ${ }^{55}$ except for $R S / S R-6$, for which a 25 -fold increase in $k_{\mathrm{d}}$ is observed due to the combination of IHB suppression and intimate ion pair dissociation.

## Effect of protonation on $\boldsymbol{k}_{\mathbf{d}}$

A $c a .10$-fold and 60 -fold increase in $k_{\mathrm{d}}$ for 12 in $t$-BuPh and water $/ \mathrm{MeOH}$ as solvents was reported upon protonation. Amazingly, the protonation effect for 4, i.e., a ca. 6 -fold and

[^6]12-fold increase in $t$-BuPh and water/ MeOH as solvents, respectively, and that for 6 , i.e., a 3 -fold and ca. 8 -fold increase (for the $R R / S S$ diastereoisomer) in $t$ - BuPh and water/ MeOH as solvents, respectively, are less strong than that for 12, although 6 and 4 exhibit structures very similar to that of 12 ! Suppressing IHB in water/MeOH for $R S / S R-6 \mathbf{H}+$ affords a 20 -fold increase in $k_{\mathrm{d}}$ upon protonation. This surprising lower effect of protonation for $\mathbf{4}$ and $\mathbf{6}$ is ascribed to the better solvation of the alkoxyamine for 4 and 6 than that for 12, due to the presence of the hydroxyl group affording the better stabilization of the starting alkoxyamine, which partly balances the polar effect due to protonation.

## Experimental section

Alkoxyamines 3 were prepared as previously reported, ${ }^{26}$ with the modification of the first step. All solvents and reactants for the preparation of alkoxyamines were used as received. Routine reaction monitoring was performed using silica gel 60 $\mathrm{F}_{254}$ TLC plates; spots were visualized upon exposure to UV light and a phosphomolybdic acid solution in EtOH as a stain revealed by heating. Purifications were performed on a Reveleris® X2 flash chromatography system (BUCHI, Switzerland); a solvent delivery system: high pressure HPLC pumps; pump flow rate: $1-200 \mathrm{~mL} \mathrm{~min}{ }^{-1}$; maximum pressure: 200 psi; gradients: linear (see Fig. 5SI $\dagger$ for the profile); UV wavelength range: $200-500 \mathrm{~nm}$; flash Reveleris® and GraceResolv ${ }^{\mathrm{TM}}$ cartridges: silica $40 \mu \mathrm{~m}$, silica weight (g): 4, 12, $24,48,80$ and $120 .{ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$, and ${ }^{31} \mathrm{P}$ NMR spectra were recorded in $\mathrm{CDCl}_{3}$ on a 300 or 400 MHz spectrometer. Chemical shifts $(\delta)$ in ppm were reported using residual nondeuterated solvents as the internal reference for ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$-NMR spectra, and as an internal capillary filled with $85 \%$ $\mathrm{H}_{3} \mathrm{PO}_{4}$ for ${ }^{31} \mathrm{P}$-NMR spectra. High-resolution mass spectra (HRMS) were recorded on a SYNAPT G2 HDMS (Waters) spectrometer equipped with a pneumatically assisted atmospheric pressure ionization source (API). Positive mode electrospray ionization was used on samples: electrospray voltage (ISV): 2800 V ; opening voltage (OR): 20 V ; nebulizer gas pressure (nitrogen): $800 \mathrm{~L} \mathrm{~h}^{-1}$. Low resolution mass spectra were recorded on an ion trap AB SCIEX 3200 QTRAP instrument equipped with an electrospray source. The parent ion [M $+\mathrm{H}]^{+}$is quoted.

## Diethyl (1-((1-hydroxy-2-methylpropan-2-yl)amino)-2,2dimethylpropyl)phosphonate (3b)

Under $\mathrm{N}_{2}$, 2-methyl-2-aminopropanol 3a ( 6.8 g , 1.1 eq , 76.7 mmol ) was added dropwise to a solution of pivalaldehyde $(6.0 \mathrm{~g}, 1 \mathrm{eq} ., 69.7 \mathrm{mmol})$ in pentane ( 50 mL ). The solution was heated at $65{ }^{\circ} \mathrm{C}$ with a Dean-Stark device for 2 days. Then, pentane was evaporated and diethylphosphite ( $10.6 \mathrm{~g}, 1.1 \mathrm{eq}$., 76.7 mmol ) was added at r.t., and the mixture was heated at $45{ }^{\circ} \mathrm{C}$ for seven days. The solution was acidified with 1 M HCl $(50 \mathrm{~mL})$, and washed with dichloromethane $(2 \times 30 \mathrm{ml})$. The aqueous layer was basified with $\mathrm{NaHCO}_{3}$ and then extracted
with dichloromethane ( $2 \times 20 \mathrm{ml}$ ), the organic layer was dried $\left(\mathrm{MgSO}_{4}\right)$, and the solvent was evaporated to yield aminophosphonate 3b (16.1 g, 78\%). ${ }^{26}$

## Diethyl (1-((1-((tert-butyldimethylsilyl)oxy)-2-methylpropan-2-

 yl)amino)-2,2-dimethylpropyl) phosphonate (2b)The same procedure as that for $\mathbf{3 b}$ was applied to $2 \mathbf{a}$. $2 \mathbf{a}(3 \mathrm{~g}$, 1.1 eq., 16.23 mmol$)$, pivalaldehyde $(1.27 \mathrm{~g}, 1 \mathrm{eq} .$, 14.75 mmol ), pentane ( 20 mL ) and diethylphosphite ( 2.2 g , 1.1 eq., 16.23 mmol ). After flash-chromatography (gradient petroleum ether (PE)/AcOEt: $0 \%$ to $100 \%$ of AcOEt), aminophosphonate $2 \mathbf{b}$ was isolated ( $3.8 \mathrm{~g}, 64 \%$, colourless oil). ${ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta: 4.09(\mathrm{qd}, J=7.1,1.3 \mathrm{~Hz}, 4 \mathrm{H}$ ), $3.32(\mathrm{~s}, 2 \mathrm{H}), 2.81\left(\mathrm{~d}, J_{\mathrm{H}-\mathrm{P}}=17.0 \mathrm{~Hz}, 1 \mathrm{H}\right), 1.68(\mathrm{~s}, 1 \mathrm{H}), 1.30(\mathrm{t}$, $J=7.1 \mathrm{~Hz}, 6 \mathrm{H}), 1.06(\mathrm{~s}, 3 \mathrm{H}), 1.04(\mathrm{~s}, 9 \mathrm{H}), 0.99(\mathrm{~s}, 3 \mathrm{H}), 0.90(\mathrm{~s}$, $9 \mathrm{H}), 0.03(\mathrm{~s}, 6 \mathrm{H}) .{ }^{13} \mathrm{C}$ NMR ( $75 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta: 72.8$ ( $\mathrm{d}, J_{\mathrm{C}-\mathrm{P}}=$ $1.8 \mathrm{~Hz}), 61.4\left(\mathrm{~d}, J_{\mathrm{C}-\mathrm{P}}=7.4 \mathrm{~Hz}\right), 61.0\left(\mathrm{~d}, J_{\mathrm{C}-\mathrm{P}}=7.6 \mathrm{~Hz}\right), 58.9(\mathrm{~d}$, $\left.J_{\mathrm{C}-\mathrm{P}}=138.7 \mathrm{~Hz}\right), 54.2\left(\mathrm{~d}, J_{\mathrm{C}-\mathrm{P}}=1.6 \mathrm{~Hz}\right), 35.2,35.1,27.9(\mathrm{~d}$, $\left.J_{\mathrm{C}-\mathrm{P}}=6.2 \mathrm{~Hz}, 2 \mathrm{C}\right), 25.9(3 \mathrm{C}), 25.1\left(\mathrm{~d}, J_{\mathrm{C}-\mathrm{P}}=1.5 \mathrm{~Hz}\right), 24.2,18.2$, $16.5\left(\mathrm{~d}, J_{\mathrm{C}-\mathrm{P}}=4.6 \mathrm{~Hz}\right), 16.4\left(\mathrm{~d}, J_{\mathrm{C}-\mathrm{P}}=5.0 \mathrm{~Hz}\right),-5.5(2 \mathrm{C})$. ${ }^{31} \mathrm{P}$ NMR ( $162 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta: 30.09$. HRMS $\mathrm{m} / \mathrm{z}$ (ESI) calcd for $\mathrm{C}_{19} \mathrm{H}_{45} \mathrm{NO}_{4} \mathrm{PSi}[\mathrm{M}+\mathrm{H}]^{+} 410.2850$, found: 410.2852 .

## (1-(Diethoxyphosphoryl)-2,2-dimethylpropyl)-(2-

((tert-butyldimethylsilyl)oxy)-1,1-dimethylethyl)amino- N -oxyl radical ( $2^{\circ}$ )
Aminophosphonate $2 \mathbf{2 b}(1.0 \mathrm{~g}, 1$ eq., 2.4 mmol$)$ was dissolved in a mixture of $\mathrm{EtOH} / \mathrm{H}_{2} \mathrm{O}(3: 1)(15 \mathrm{~mL})$ and $\mathrm{Na}_{2} \mathrm{CO}_{3}(1.55 \mathrm{~g}$, 6 eq., 14.6 mmol ). Then, Oxone® ( $3.0 \mathrm{~g}, 4$ eq., 9.8 mmol ) was added in small portions at r.t. within 2 h under vigorous stirring. After completion, $\mathrm{Et}_{2} \mathrm{O}(10 \mathrm{ml})$ was added, and the precipitate was filtered off. $\mathrm{Et}_{2} \mathrm{O}$ was removed under vacuum. The aqueous phase was extracted with dichloromethane $(2 \times 15 \mathrm{ml})$, and dried over $\mathrm{MgSO}_{4}$ and the solvents were evaporated under reduced pressure. The crude was purified by flash chromatography (gradient PE/AcOEt: $0 \%$ to $100 \%$ of AcOEt) and nitroxide $2^{\circ}$ was isolated ( $529 \mathrm{mg}, 51 \%$ ). HRMS $\mathrm{m} / \mathrm{z}$ (ESI) calcd for $\mathrm{C}_{19} \mathrm{H}_{44} \mathrm{NO}_{5} \mathrm{PSi} \cdot[\mathrm{M}+\mathrm{H}]^{+}$425.2721, found: 425.2720.

## Diethyl (1-((1-((tert-butyldimethylsilyl)oxy)-2-methylpropan-2-yl)(1-phenylethoxy)amino)-2,2-dimethylpropyl) phosphonate (2)

To a suspension of $\mathrm{CuBr}(55 \mathrm{mg}, 0.55$ eq., 0.388 mmol$)$ and Cu powder ( $49 \mathrm{mg}, 1.1$ eq., 0.78 mmol ) in degassed benzene (argon bubbling for one hour) ( 3 mL ) was added $N, N, N^{\prime}, N^{\prime}, N^{\prime \prime}-$ pentamethyldiethylenetriamine ( $80 \mu \mathrm{~L}, 0.55$ eq., 0.39 mmol ). After stirring for 10 min , a solution of nitroxide $2^{\circ}(300 \mathrm{mg}$, $1 \mathrm{eq} ., 0.71 \mathrm{mmol}$ ) and (1-bromoethyl)benzene ( $103 \mu \mathrm{~L}, 1.1 \mathrm{eq}$. , 0.78 mmol ) in degassed benzene ( 3 mL ) was transferred to the first solution. The mixture was allowed to stir for 12 h . The solution was diluted with $\mathrm{Et}_{2} \mathrm{O}$, quenched with a $\mathrm{NH}_{4} \mathrm{Cl}$ sat. solution, washed with water and brine, and dried over $\mathrm{MgSO}_{4}$. The solvents were evaporated under reduced pressure to give the crude product as a $1: 1$ mixture of diastereoisomers ( ${ }^{31} \mathrm{P}$-NMR ratio). The crude product was purified by automatic
flash-chromatography (gradient PE/AcOEt: 0\% to $100 \%$ of AcOEt) to yield alkoxyamines $R R / S S-2$ (pale yellow oil, 119 mg , $32 \%$ ) and $R S / S R-2$ (pale yellow oil $123 \mathrm{mg}, 33 \%$ ). $R S / S R-2$ ${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta: 7.37(\mathrm{~d}, J=7.3 \mathrm{~Hz}, 2 \mathrm{H}), 7.17$ (m, $3 \mathrm{H}), 5.18(\mathrm{q}, J=6.4 \mathrm{~Hz}, 1 \mathrm{H}), 3.86(\mathrm{~m}, 2 \mathrm{H}), 3.69\left(\mathrm{~d}, J_{\mathrm{H}-\mathrm{P}}=\right.$ $26.6 \mathrm{~Hz}, 1 \mathrm{H}), 3.58(\mathrm{~s}, 2 \mathrm{H}), 3.38(\mathrm{~m}, 1 \mathrm{H}), 3.21(\mathrm{~m}, 1 \mathrm{H}), 1.48(\mathrm{~d}$, $J=6.5 \mathrm{~Hz}, 3 \mathrm{H}), 1.15(\mathrm{~m}, 18 \mathrm{H}), 0.86(\mathrm{~m}, 12 \mathrm{H}), 0.00(\mathrm{~s}, 6 \mathrm{H}) .{ }^{13} \mathrm{C}$ NMR ( $75 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta: 143.2,127.9$ (2C), 127.7 (2C), 127.3, $78.5,70.0\left(\mathrm{~d}, J_{\mathrm{C}-\mathrm{P}}=139.2 \mathrm{~Hz}\right), 69.0,65.1,61.6\left(\mathrm{~d}, J_{\mathrm{C}-\mathrm{P}}=6.4 \mathrm{~Hz}\right)$, $58.5\left(\mathrm{~d}, J_{\mathrm{C}-\mathrm{P}}=7.5 \mathrm{~Hz}\right), 35.4\left(\mathrm{~d}, J_{\mathrm{C}-\mathrm{P}}=5.3 \mathrm{~Hz}\right), 30.5\left(\mathrm{~d}, J_{\mathrm{C}-\mathrm{P}}=\right.$ 6.0 Hz, 2C), 25.9 (3C), 23.4, 22.6, 21.2, 18.2, 16.3 (d, $J_{\mathrm{C}-\mathrm{P}}=$ $5.6 \mathrm{~Hz}), 16.1\left(\mathrm{~d}, J_{\mathrm{C}-\mathrm{P}}=6.9 \mathrm{~Hz}\right),-5.4,-5.5 .{ }^{1} \mathrm{P}$ NMR ( 121 MHz , $\mathrm{CDCl}_{3}$ ) $\delta: 24.98 . ## General procedure for TBS protection of alcohols $3 \mathbf{a}, 3 \mathrm{~b}$ and

 $3^{32,56}$In a flask under $\mathrm{N}_{2}$, alcohols 3a, 3b or 3 (1.0 eq.), tert-butyldimethylsilyl trifluoromethanesulfonate ( 1.5 eq .) and 2,6-lutidine ( 2 eq.) were stirred in dichloromethane at room temperature for 4 hours. A saturated $\mathrm{NaHCO}_{3}$ solution was added and the layers were separated. The organic layer was dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered, and concentrated in vacuo. Purification was performed using flash chromatography, affording $\mathbf{2 a}, \mathbf{2 b}$, or 2 as an oil.

## Hydrolysis ${ }^{31}$ of silylated compound 2

In a flask under $\mathrm{N}_{2}, R R / S S-2$ or $R S / S R-2$ ( $30 \mathrm{mg}, 1$ eq., 0.06 mmol ) was dissolved in THF ( 2 mL ), and tetra- $n$-butylammonium fluoride ( 1 M in THF) was added ( $68 \mu \mathrm{~L}, 1.2 \mathrm{eq}$., 0.07 mmol ). After stirring for 1 hour at room temperature, THF was evaporated under reduced pressure and the crude was purified by automatic flash-chromatography (gradient PE/ AcOEt: $0 \%$ to $100 \%$ of AcOEt) to yield alkoxyamine $R R / S S-3^{\prime}$ or $R S / S R-3$ ' with a yield higher than $90 \%$.

## Diethyl-(1-((1-hydroxy-2-methylpropan-2-yl)(1-(pyridin-2-yl) ethoxy)amino)-2,2-dimethylpropyl) phosphonate (4)

In an open flask, $\mathrm{MnCl}_{2}$ ( $70 \mathrm{mg}, 0.05$ eq., 0.35 mmol ) was added to a stirred solution of salen ligand ( $130 \mathrm{mg}, 0.05 \mathrm{eq}$., 0.35 mmol ) in i-PrOH. After 30 minutes of stirring at room temperature, a solution of $3^{\circ}(2.2 \mathrm{~g}, 1 \mathrm{eq} ., 7.1 \mathrm{mmol})$ and 2-vinylpyridine ( $1.15 \mathrm{~mL}, 1.5 \mathrm{eq} ., 10.6 \mathrm{mmol}$ ) in i-PrOH was added first, and then solid $\mathrm{NaBH}_{4}(1.07 \mathrm{~g}, 4$ eq., 28.4 mmol$)$ was added in small portions. The resulting suspension was stirred at room temperature for 4 h . It was then diluted with

EtOAc and 1 M aq. HCl was carefully added. Solid $\mathrm{NaHCO}_{3}$ was then added until neutralization. The layers were separated, and the organic phase was washed with water and brine, and dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$. The solvent was evaporated to give the crude product as a 1:2 mixture of diastereoisomers ( ${ }^{31} \mathrm{P}-\mathrm{NMR}$ ratio). The diastereomers were separated by automatic flash column chromatography (gradient PE/AcOEt: $0 \%$ to $100 \%$ of AcOEt) to afford $R R / S S-4$ (pale yellow crystal $560 \mathrm{mg}, 19 \%$ ) and $R S / S R-4$ (pale yellow oil $1.01 \mathrm{~g} 35 \%$ ). $R S / S R-4{ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta: 8.44(\mathrm{dd}, J=5.1,1.7 \mathrm{~Hz}, 1 \mathrm{H}), 7.59(\mathrm{td}, J=$ $7.7,1.8 \mathrm{~Hz}, 1 \mathrm{H}), 7.45(\mathrm{~d}, J=7.8 \mathrm{~Hz}, 1 \mathrm{H}), 7.07$ (ddd, $J=7.6,4.8$, $1.2 \mathrm{~Hz}, 1 \mathrm{H}), 5.20(\mathrm{q}, J=6.5 \mathrm{~Hz}, 1 \mathrm{H}), 3.89(\mathrm{~d}, J=12.7 \mathrm{~Hz}, 1 \mathrm{H})$, $3.67(\mathrm{~m}, 4 \mathrm{H}), 3.57\left(\mathrm{~d}, J_{\mathrm{H}-\mathrm{P}}=26.5 \mathrm{~Hz}, 1 \mathrm{H}\right), 3.44(\mathrm{~d}, J=12.6 \mathrm{~Hz}$, $1 \mathrm{H}), 1.57(\mathrm{~d}, J=6.6 \mathrm{~Hz}, 3 \mathrm{H}), 1.12(\mathrm{~s}, 3 \mathrm{H}), 1.10(\mathrm{~s}, 9 \mathrm{H}), 1.09(\mathrm{~s}$, $3 \mathrm{H}), 1.04(\mathrm{t}, J=7.1 \mathrm{~Hz}, 3 \mathrm{H}), 0.98(\mathrm{t}, J=7.1 \mathrm{~Hz}, 3 \mathrm{H}) .{ }^{13} \mathrm{C}$ NMR $\left(75 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta: 162.1,148.6,136.9,122.3,121.6,78.7,70.5$ $\left(\mathrm{d}, J_{\mathrm{C}-\mathrm{P}}=136.3 \mathrm{~Hz}\right), 70.0,64.9,61.7\left(\mathrm{~d}, J_{\mathrm{C}-\mathrm{P}}=6.6 \mathrm{~Hz}\right), 60.1(\mathrm{~d}$, $\left.J_{\mathrm{C}-\mathrm{P}}=7.9 \mathrm{~Hz}\right), 35.3\left(\mathrm{~d}, J_{\mathrm{C}-\mathrm{P}}=4.0 \mathrm{~Hz}\right), 30.6\left(\mathrm{~d}, J_{\mathrm{C}-\mathrm{P}}=5.7 \mathrm{~Hz}, 3 \mathrm{C}\right)$, $26.9,22.0,20.4,16.4\left(\mathrm{~d}, J_{\mathrm{C}-\mathrm{P}}=5.7 \mathrm{~Hz}\right), 15.9\left(\mathrm{~d}, J_{\mathrm{C}-\mathrm{P}}=6.8 \mathrm{~Hz}\right)$. ${ }^{31} \mathrm{P}$ NMR ( $121 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta: 26.13$. ## Kinetic measurements

The values of the homolysis rate constant $k_{\mathrm{d}}$ were determined
by monitoring either the concentration of nitroxide by EPR or the concentration of alkoxyamine by ${ }^{31} \mathrm{P}$ NMR. For EPR, a sample tube filled with a solution of $10^{-4} \mathrm{M}$ of each diastereoisomer in tert-butylbenzene or in $\mathrm{H}_{2} \mathrm{O} / \mathrm{MeOH}(1: 1)$ was set in the EPR cavity. EPR signals were recorded. The temperature was controlled by using a BVT2000 temperature controlling unit. Measurements of $k_{\mathrm{d}}$ by ${ }^{31} \mathrm{P}$ NMR required the use of TEMPO as an alkyl radical scavenger. The NMR tubes were filled with a stock solution of 0.02 M of alkoxyamine in tertbutylbenzene or in $\mathrm{H}_{2} \mathrm{O} / \mathrm{MeOH}$ with 2 equiv. of TEMPO. Buffer solutions were used for specific pH conditions instead of $\mathrm{H}_{2} \mathrm{O}$. $k_{\mathrm{d}}$ values were given by eqn (4). Activation energies $E_{\mathrm{a}}$ were estimated using eqn (5) and the average frequency factor $A=$ $2.4 \times 10^{14} \mathrm{~s}^{-1}$. The values of $k_{\mathrm{d}}$ and $E_{\mathrm{a}}$ are listed in Table 4.

$$
\begin{gather*}
\ln \frac{[\text { alkoxyamine }]_{t}}{[\text { alkoxyamine }]_{0}}=-k_{\mathrm{d}} t  \tag{4}\\
k_{\mathrm{d}}=A \mathrm{e}^{-E_{\mathrm{a}} / R T} \tag{5}
\end{gather*}
$$

## Conclusion

Different types of IHBs exhibiting very different effects are highlighted. These effects depend on the strength of the IHB,
which in turn is straightforwardly related to its geometric parameters $-d_{\mathrm{OH} \cdots \mathrm{x}}$ the distance for IHB and the IHB valence angle $\alpha$. That is, strong interR IHBs are expected for $\alpha$ larger than $160^{\circ}$ and $d_{\mathrm{OH} \cdots \mathrm{x}}$ smaller than $1.8 \AA$ affording an increase in $E_{\mathrm{a}}$ (Tables 4 and 5). As geometric parameters $-\alpha \approx 150^{\circ}$ and $d_{\mathrm{OH} \cdots \mathrm{x}} \approx 2.1 \AA$ - underline a weak IHB, inter $N$ IHB does not exhibit the same effect as that of interR IHB. Indeed, this interN IHB is weak enough that it is in equilibrium with the intraN IHB which, in turn, favours slightly the C-ON bond homolysis, i.e., decreasing $E_{\mathrm{a}}$. Nevertheless, a strong interN IHB is expected to afford the same effect as that of a strong interR IHB. IntraN and intraR IHBs exhibit features of IHB of intermediate strength $-\alpha<150^{\circ}$ and $d_{\mathrm{OH} \cdots \mathrm{x}}>1.8 \AA$ - affording a decrease in $E_{\mathrm{a}}$. However, the effect of intraR and intraN depends a lot on the strength of these IHBs at TS, that is, on the stereoelectronic requirement for the C-ON bond homolysis and on the stabilization of the products, i.e., partly due to the strength of IHB. Hence, stronger IHBs in products than in starting materials stabilize TS and decrease $E_{\mathrm{a}}$. This assumption is supported by the stronger IHB in $3^{\circ}\left(\alpha=178^{\circ}\right.$ and $d_{\mathrm{OH} \cdots \mathrm{X}}=1.57 \AA$ ) than in 3 and 4 (Table 5) $++1^{57}$

As a rule of thumb, one may assume that IHB between alkyl and nitroxyl fragments (interN or interR IHB) affords an increase in $E_{\mathrm{a}}$ which might be pictured as the cleavage of two bonds - C-ON bond and IHB - and that IHB inside each fragment (intraN or intraR IHB) affords a slight decrease in $E_{\text {a }}$ provided the stabilization due to IHB is larger for the released radicals than that for the starting material. Otherwise, an increase in $E_{\mathrm{a}}$ might be expected.

This work highlights the combination of several effects IHB, solvents, intimate ion pairs, and protonation - to strikingly decrease the alkoxyamine half-life time $t_{1 / 2}$, as highlighted by $t_{1 / 2}=123$ days for 6 in $t$-BuPh as a solvent at $37^{\circ} \mathrm{C}$ and by $t_{1 / 2}=14$ hours for $\mathbf{6 H}+$ in water $/ \mathrm{MeOH}$ as a solvent at $37^{\circ} \mathrm{C}$, that is, a 210 -fold increase in $k_{\mathrm{d}}$. These results nicely highlight the potential of such alkoxyamines as switches for applications in biology. ${ }^{17}$

## Conflicts of interest

There are no conflicts of interest to declare.

## Acknowledgements

SRAM, PB, VR and GA thank Aix-Marseille Université and CNRS for support. SRAM and ME are grateful to the Russian Science Foundation (grant 15-13-20020) for supporting this work and to the Multi-Access Chemical Service Center SB RAS for spectral and analytical measurements. SRAM, VR, GA and JPJ are grateful to ANR for funding this project (ANR-14-CE16-0023-01). PN thanks the Ministère de la Recherche du Gabon.

    $\dagger$ Electronic supplementary information (ESI) available: ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ NMR and HRMS spectra of $2-7$ and $2^{\circ}$. DFT calculations for the most stable conformers of 4 and 6. A gradient profile for flash chromatography. The titration curve for 2 -hydroxyethylpyridine, and XRD for $R R / S S-4$ and $R S / S R-6$. CCDC 1550955 and 1550956. For ESI and crystallographic data in CIF or other electronic format see DOI: 10.1039/c7ob02223a

[^1]:    $\ddagger$ CCDC: 1550955 for $R R / S S-4$ and 1550956 for $R S / S R-6 . \dagger$
    $\S$ The procedure described in Scheme 2 was not used because it afforded the isomerization of the pure diastereoisomer.

[^2]:    $\dagger \dagger$ Conformer $\mathbf{A}$ exhibiting IHB between HO and $\mathrm{P}=\mathrm{O}$ functions, conformer $\mathbf{B}$ exhibiting IHB between the OH function and N atom, and C the most stable conformer with no IHB.

[^3]:    $\ddagger \ddagger$ Indeed, conformer A exhibits geometrical parameters (Table 5) featuring stronger IHB than in B as highlighted by the shorter $d_{\mathrm{OH} \ldots \mathrm{OP}}$ and flatter angle $\alpha$ for $R R / S S-6$.
    $\S \S$ When the $t$-Bu group attached to the nitroxyl moiety is replaced by a bulkier group $\mathrm{CMe}_{2} \mathrm{R}$, no difference in $k_{\mathrm{d}}$ is observed, meaning that the nitroxyl fragment adopts a conformation which forces the R group to be in such a position that its bulkiness is cancelled. This is due to the levelled steric effect. See ref. 43-46.

[^4]:    94In ref. 29, no intraN IHB is observed in X-ray data.
    |||| Indeed, a 3-center IHB (Fig. 8) would require a conformation for the aromatic ring exhibiting a $1,3-$ syn allylic destabilizing interaction with H10, whereas such an interaction does not occur for conformers $\mathbf{A}$ and $\mathbf{B}$.

[^5]:    *** The weak effect of IHB in $R R / S S-6$ is due to a weak IHB (the weakest of those investigated), as highlighted by its longest $d_{\mathrm{OH} \cdots \mathrm{x}}$ and its closed angle $\alpha$.

[^6]:    $\dagger \dagger$ For such molecules, a difference of $2.5 \mathrm{~kJ} \mathrm{~mol}^{-1}$ in energy is in the limit of accuracy and reliability of the method.

[^7]:    $\ddagger \ddagger$ A similar effect on remote IHB has already been reported in ref. 57. The authors would like to thank the reviewer for pointing this issue at TS.
