HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Diastereoselective Synthesis of Potent Antimalarial *Cis*- β -lactam Agents

Abstract

Fifteen novel β -lactams bearing N-ethyl tert-butyl carbamate group **5a-o** and fifteen N-(2-aminoethyl) β -lactams **6a-o** were synthesized by [2+2] ketene-imine cycloaddition reaction (Staudinger). The cycloaddition reaction was found to be totally diastereoselective leading exclusively to the formation of *cis*- β -lactam derivatives. These newly synthesized β -lactams were evaluated for their antimalarial activity against *P. falciparum* K14 resistant strain and showed good to excellent EC₅₀ values. Of the thirty β -lactams tested, **5 h**, **6a** and **6c** showed IC₅₀ < 20 μ M while **5b**, **5c**, **5e**, **5f**, **5g**, **5i**, **5j**, **6d**, **6g** and **6h** exhibited IC₅₀ < 50 . Compounds **5c**, **5h**, and **5q-t** were examined for their anticancer properties against K562 *Leukemia* cell line and **5s** showed the best activity. Compounds **3a-j**, **5a-o**, **6a-o**, were tested against *S. aureus*, *E. coli*, *C. albicans* and showed no activity below 125 μ g/mL.

Keywords: N -(2-aminoethyl) β -lactams; tert-butyl carbamate; 2-Azetidinones; *P. falciparum*; Staudinger; Antimalarial activity.

Introduction

Malaria has been a serious public disease for many decades. The development of resistance by *plasmodium falciparum* to drugs such as chloroquine and quinine requires the discovery and development of new drugs (1). A new diterpenoid β -lactam alkaloid showing potent antimalarial activity has been isolated from marine sponge *Hymeniacidon* sp by Rodriguez and his coworker (2). Due to spread of resistance in the mosquito vector to currently available insecticides the control of malaria is becoming

more complicated. Therefore, it is necessary to synthesize new classes of antimalarials (3), and to develop them as drugs with varied models of action to overcome the problem of resistance (4). The development of a novel class of antimalarials derived from β -lactam has initiated in recent years (5-6). β -Lactam derivatives with various functional groups have played an important role in antibacterial drugs and in medicinal chemistry (7). The β -lactam ring is an important structural element of the most widely employed β -lactam antibiotics family (8), which includes representative structural classes; penams, cepems, penems, monobactams, carbapenems, and trinems (9). In addition, β -lactams show many important non-antibiotic biological

* Corresponding author: E-mail: jarahpor@shirazu.ac.ir

activities (10). They also have increasingly being used as valuable starting materials to develop new synthetic methodologies (11-12). The constant need for potent and effective β -lactam antibiotics as well as more effective β -lactamase inhibitors has prompted synthetic organic and medicinal chemist to design new functionalized

2-azetidinones. There are a large number of synthetic methods for the preparation of β -lactams (13), for which the [2+2] cycloaddition of ketenes with imines (the Staudinger reaction) is the most important method for constructing the 2-azetidinone ring (14).

Experimental

General

All needed chemicals were purchased from Merck, Fluka and Acros. All reagents and solvents were dried prior to use according to standard methods. IR spectra were run on a Shimadzu FT-IR 8300 spectrophotometer. $^1\text{H-NMR}$ and $^{13}\text{C-NMR}$ spectra were recorded in DMSO-d_6 or CDCl_3 using a Bruker Avance DPX instrument ($^1\text{H-NMR}$ 250 MHz, $^{13}\text{C-NMR}$ 62.9 MHz). Chemical shifts were reported in parts per million (δ) downfield from TMS. All of the coupling constants (J) are in hertz. The mass spectra were recorded on a Shimadzu GC-MS QP 1000 EX instrument. Elemental analyses were run on a Thermo Finnigan Flash EA-1112 series. Melting points were determined in open capillaries with Buchi 510 melting point apparatus. Thin-layer chromatography was carried out on silica gel F254 analytical sheets obtained from Fluka. Column chromatography was performed on Merck Kiesel gel (230–270 mesh).

General Procedure for Preparation of Schiff Bases 3a-j

A solution of N-tert-butoxycarbonyl-1, 2-ethanediamine (0.50 g, 3.10 mmol) in anhydrous CH_2Cl_2 (25 mL) was treated with different aldehydes (3.10 mmol) in the presence of anhydrous MgSO_4 (6.00 g). The reaction mixture was stirred at room temp for 16 h, filtered and the solvent eliminated under vacuum to give crude Schiff bases 3a-j. They were used for next stage without further purification.

General procedure for the synthesis of monocyclic β -lactams 5a-o

A solution of acyl chloride (1.2 mmol) in dry CH_2Cl_2 (10 mL) was slowly added to a solution of Schiff bases (1.0 mmol) and triethylamine (2 mmol) in CH_2Cl_2 (15 mL) at -82°C . The reaction mixture was then allowed to warm to room temperature, stirred overnight and then the solution was washed successively with HCl 1N (20 mL), saturated NaHCO_3 (20 mL), and brine (20 mL). Then, it was dried over Na_2SO_4 and then filtered. The solvent was evaporated under reduced pressure to give the crude product. All β -Lactams were purified by recrystallization from EtOH, EtOAc except 5j which was purified by column chromatography ethyl acetate / petroleum ether (1:2).

General procedure for the deprotection of BOC protecting group

A solution of β -lactams (**5a-o**) (0.5 mmol) in CH_2Cl_2 (12 mL) was cooled to 0 $^\circ\text{C}$ and treated with TFA (3-5 mmol). After the addition, the cooling bath was removed and stirring was continued until total disappearance of the starting material (TLC). Then the solution was basified with 5% aqueous NaOH solution (pH = 10). The organic layer was separated, and the aqueous layer was extracted with CH_2Cl_2 (2 \times 30 mL). The combined extracts were washed with brine, dried over Na_2SO_4 , and concentrated to give crude N-(2-aminoethyl) β -lactams **6a-o**.

General procedure for antimalarial activity measurements

The chloroquine-resistant *P. falciparum* strain K14 (Southeast Asia) was cultured in vitro in complete medium consisting of RPMI 1640 (In Vitrogen) supplemented with 27.5 mM NaHCO_3 , 20 mg/L gentamycin, and 10% human serum (19). Parasites were grown at 37 °C in human O+ red blood cells at a 6% hematocrit under a 5% CO_2 , 10% O_2 and 85% N_2 atmosphere. Cultures were synchronized by sorbitol treatments (20). Stock solutions of lactam derivatives were prepared in sterile DMSO (10 mM) and later dilutions were with complete culture medium. Increasing concentrations of lactam derivatives (100 μL /well, top concentration = 50 μM) were distributed in a 96-well plate; DMSO (0.5% vol/vol, top concentration) was distributed for control. Then, 100 μL from a culture containing > 95% ring (0-20 h postinvasion) at a 0.8% parasitemia and 3% haematocrit in complete medium was added per well along with 1.0 μCi of 3H-hypoxanthine with a specific activity of 14.1 Ci/mmol (Perkin-Elmer, Courtaboeuf, France). Parasites were grown for 42 h at 37 °C. Plates were then freeze-thawed and harvested on filters. Dried filters were moistened in scintillation liquid mixture (Microscint O; Perkin-Elmer) and counted in a Top Count Microbeta counter (Perkin-Elmer). Percentage growth inhibition was calculated from the parasite-associated radioactivity. 100% 3H-hypoxanthine incorporation was determined from a control grown in the absence of lactam derivatives. The concentration of drug giving 50% inhibition of label incorporation (IC50) was determined by nonlinear regression analysis of log-based dose-response curve (Riasmart; Packard). Each concentration was estimated from independent experiments in triplicate.

Results and discussion

A mixture of amine 1 which was prepared from

(ATCC64025), *S. aureus* (ATCC 25923) and *E. coli* (ATCC 25922) showing no activity below 256 μ g/mL

Anticancer activity

Compounds **5c**, **5h** and **5q-t**, were examined for their anticancer properties against K562 *Leukemia* cell line at two different concentrations (50 and 100 μ g/mL) and **5s** showed the best activity.

Antimalarial activity

Good to excellent antimalarial activities have been obtained against chloroquine resistant *p. falciparum* K14 strain as outlined in Table 2 for *cis*-2-azetidinones **5a-o** and β -lactams **6a-o** with IC₅₀ varying from 15 to 50 μ M in the better cases. Thus, even if the mechanism of action of these compounds remains unknown some structure-activity relationships can be underlined. Firstly, it is noteworthy that the less active derivatives **5k-5o** and **6k-6o** differ from the other derivatives by the replacement on the lactam ring of a phenoxy group by a methoxy one suggesting

a dramatic contribution of this moiety on the encountered antimalarial activity. On the other hand, a slight change such as removal of the BOC protecting group led to an increase of the biological activity of compounds **6a** and **6d** (IC₅₀ = 19 and 22 μ M respectively) whereas their protected parent derivatives are totally inactive suggesting here again a quite strong influence of the structure of the considered lactam derivative on the mechanism of action.

Conclusion

In this study, thirty novel β -lactams bearing the N-ethyl tert-butyl carbamate and N-(2-aminoethyl) β -lactams were synthesized by [2+2] ketene-imine cycloaddition reaction (Staudinger). The cycloaddition reaction was found to be totally diastereoselective leading exclusively to formation of *cis*- β -lactam derivatives. These newly synthesized β -lactams were evaluated for their antimalarial activity against *p. falciparum* K14 resistant strain and showed good to excellent EC₅₀ values. Of the

thirty β -lactams tested, **5h**, **6a** and **6c** showed $IC_{50} < 20 \mu M$ while **5b**, **5c**, **5e**, **5f**, **5g**, **5i**, **5j**, **6d**, **6g** and **6h** exhibited $IC_{50} < 50$. Compounds **5c**, **5h**, and **5q-t** were examined for their anticancer properties against K562 *Leukemia* cell line and **5s** showed the best activity. Compounds **3a-j**, **5a-o**, **6a-o** were tested against *S. aureus* (ATCC 25923), *E. coli* (ATCC 25922), *C. albicans* (ATCC10261) and showed no activity below $125 \mu g/mL$.
