Abstract

The present study examined cross-linguistic differences in morphological processing in the visual and auditory modality. French and German adults performed a visual and auditory lexical decision task that involved the same translation-equivalent items. The focus of the study was on nonwords, which were constructed in a way that the independent role of stems and suffixes in visual and auditory processing could be investigated. Results revealed a stem-by-modality and a suffix-by-modality interaction, indicating a more prominent role for morphology in the visual than in the auditory domain. Moreover, a significant language-by-stem interaction indicated more robust morphological processing in German than in French. The latter result supports the idea that morphological processing is influenced by the morphological productivity of a language.

Keywords: morphological processing, cross-linguistic, visual lexical decision; auditory lexical decision

How morphologically complex words are processed has been extensively investigated over the past few decades. However, few studies have investigated this issue across languages and modalities. The present study was designed to address two questions that have so far received little attention in the literature. The first question concerns if and how mechanisms of morphological processing differ depending on whether the input stimulus is a printed letter string or a speech signal. The second question asks how these mechanisms might differ across languages that vary in morphological productivity. Addressing these questions has the potential to advance theories of morphological processing by providing a broader modality-independent and language-universal perspective. The present study uses an innovative approach to answer each of these questions.

Morphological processing across modalities

In many Indo-European languages with concatenative morphology, sound-to-meaning mappings of morphologically complex words are typically less consistent than spelling-to-meaning mappings (e.g., Berg & Aronoff, 2017; Berg, Buchmann, Dybiec, & Fuhrhop, 2014; Rastle, 2018; Ulicheva, Harvey, Aronoff, & Rastle, 2018). For instance, in spoken English, the past tense is usually denoted by the allomorphs /əd/, /d/, or /t/ depending on surrounding context (e.g., *busted*, *snored*, *kicked*), whereas in written English, the corresponding phonemic sequences are always spelled *ed* (e.g., Carney, 1994; Desrochers, Manolitsis, Gaudreau, & Georgiou, 2017; Rastle, 2018). Similarly, the spelling of stems is preserved (e.g., *magic*, *magical*, *magician*), although this compromises the correspondence to their spoken forms (Treiman & Bourassa, 2000). The greater orthographic consistency of morphology in the written modality at the cost of spelling-to-sound consistency is also evident in German and French (e.g., Desrochers et al., 2017; Kuo & Anderson, 2006; Peereman, Sprenger-Charolles, & Messaoud-Galusi, 2013). In

German, for example, the written form of morphologically related words (e.g., *Sand-sandig*, “*sand-sandy*”) is preserved even when the spoken form varies (/zant/-/zandɪk/), where the ‘d’ in ‘Sand’ is pronounced /t/ due to devoicing (see also Landerl & Reitsma, 2005). Similarly in French, the spellings of morphologically complex words and their embedded stems are typically consistent (e.g. *dent-dentier*, “*tooth-dentist*”), whereas phonological forms tend to be more variable (e.g., the silent stem-final consonant ‘t’ in ‘dent’ is pronounced when a suffix is added to the stem). The consistent spelling of morphemes enables the reader to identify morphological relationships between words, although the pronunciations of words belonging to the same morphological family may vary. Diachronic data on the evolution of suffix spellings from Old English indeed show that before the 16th Century, adjectives were commonly spelled with the suffixes *-ouse*, *-us*, or *-ows*, but were then replaced with *-ous* over time (Berg & Aronoff, 2017), thus making morphology highly visible in print (see Fuhrhop, 2011, for a similar phenomenon in German).

Of course, this does not necessarily imply that auditory and visual morphological representations in languages such as English, German and French are unrelated. There is plenty of evidence that spoken word knowledge influences reading processes (e.g., Beyersmann et al., in press; Johnston, McKague, & Pratt, 2004; McKague, Davis, Pratt, & Johnston, 2008; Wegener et al., 2018); and vice versa, it has been shown that reading has an impact on the processing of spoken language (for a review of the evidence, see Grainger & Ziegler, 2008; see also Pollatsek & Treiman, 2015). Undoubtedly, there is an obvious transfer of written language knowledge to spoken language processing and vice versa (e.g., Frost & Ziegler, 2007). However, given the greater consistency of morphology in print, it is possible that skilled readers acquire a specialized and highly automatized morphological parsing system, which is sensitive to the presence of

morphological regularities during orthographic exposure. In spoken language on the other hand, morphological processing is unlikely to reach the same level of specialization, at least in languages where the link between morphologically complex spoken forms and their embedded morphemic constituents is often inconsistent, and as such, the identification of morphological structure is less reliable. Therefore, an important question that arises is whether morphological processing is more prominent and more automatized in written compared to spoken word recognition. We sought to answer this question in the present study.

Most studies to date have examined morphological processing either in written or in spoken language using a variety of experimental paradigms (for a recent review of the literature, see Beyersmann et al., 2019). However, rarely has a study directly compared morphological processing in the visual and auditory modality. Findings from the visual word recognition domain suggest that adults are experts at rapidly and automatically identifying morphological structures in print, independently of semantics (e.g., Amenta & Crepaldi, 2012; Beyersmann, Ziegler, et al., 2016; Longtin, Segui, & Hallé, 2003; Rastle & Davis, 2008; Rastle, Davis, & New, 2004). In contrast, a review of the spoken word recognition literature (Beyersmann et al., 2019) indicates that morphological processing may be more reliant on semantics in this modality (Marslen-Wilson, Tyler, Waksler, & Older, 1994; Meunier & Longtin, 2007; Wurm, 1997, 2000; Wurm & Ross, 2001). In other words, on the basis of the available empirical evidence, form-based morphological processing is likely to be more prominent in visual than in auditory word identification.

To our knowledge, only one study so far has directly tested differences in morphological processing between the spoken and written modality (Leinonen et al., 2009). In a visual and auditory lexical decision task, in which event-related potentials (ERPs) were additionally

recorded, Leinonen et al. (2009) sought to investigate the processing of inflected Finnish words (compared to monomorphemic words) and inflected nonwords consisting of a nonword stem and an inflectional suffix (compared to monomorphemic nonwords consisting of a nonword stem and a non-morphemic ending). The behavioral results from both types of tasks showed that participants responded more slowly to inflected words compared to monomorphemic words, but there was no difference between the two types of nonwords. This pattern was also reflected in the ERP analyses, where inflected words elicited a more negative N400 compared to monomorphemic words. The single word N400 component is generally thought to reflect word form processing difficulty (e.g., Perre, Midgley, & Ziegler, 2009; Winsler, Midgley, Grainger, & Holcomb, 2018), with N400 amplitude increasing with an increased difficulty in identifying words and associating them with meaning (e.g., Grainger & Holcomb, 2009). The greater N400 for inflected words compared to monomorphemic ones was obtained in both modalities, which the authors interpreted as processing costs associated with access and possible integration of the stem and suffix. Leinonen et al. (2009) also reported a significant N400 effect in the inflected nonwords relative to their monomorphemic nonword counterparts, which was significant in the visual but not in the auditory modality. Thus, the ERP results from this study provide some initial evidence that morphological structure may have more impact on visual than on auditory processing.

Morphological processing across languages

Given that Finnish is a morphologically productive language, it is possible that the effects observed by Leinonen et al. (2009) were due to the prominent role of morphology in Finnish. This relates to the second question we addressed in this study, which is whether morphological processing in the visual and auditory modality may be modulated by the morphological

productivity of a language. Morphological productivity refers to how specific morphological word-formation patterns may be used in the production of new forms (Bauer, 2001). Morphemic units (including both affixes and stem morphemes) display large variability in morphological productivity (Hay & Baayen, 2002). The more often a morpheme occurs in morphologically complex forms in the lexicon, the more productive this morpheme is thought to be. Critically, languages differ in this respect, and attempts to quantify morphological productivity across different alphabetic orthographies (for a review, see Borleffs, Maassen, Lyytinen, & Zwarts, 2017) have not always yielded a consistent pattern of results. However, according to at least two of the methods used in the literature, namely, Juola (1998, 2008), and the most recent and comprehensive Type-token ratio (TTR; Kettunen, 2014), French is morphologically less complex than German. It has been suggested that the abundant presence of compound words in the German language (e.g., Creutz & Lagus, 2005; Creutz, Lagus, Lindén, & Virpioja, 2005; Fleischer & Barz, 1995; Meyer, 1993) may be the reason why according to the above-mentioned methods, German appears to be so morphologically complex (Sadeniemi, Kettunen, Lindh-Knuutila, & Honkela, 2008). German compounds are mostly right-headed and concatenated (*Großvater* [engl. grandfather]), whereas French compounds are typically left-headed and non-concatenated (*chef de police* [engl. chief of police]) or hyphenated (*grand-père* [engl. grandfather]) (Nicoladis & Krott, 2007). The latter type is less frequent than the former and not very productive (Nicoladis, 2001). German also permits the compounding of multiple meaning conveying units (e.g. *Datenschutzexpertentagungshotel* [engl. Meeting hotel for data protection experts]), which are generally written without intervening spaces (e.g., Inhoff, Radach, & Heller, 2000). Given these key linguistic differences between French and German, we hypothesized that morphological processing should be more robust in German than in French. Specifically, due to

the rich compounding system that characterizes the German language, Germans should likely be more expert at rapidly extracting embedded stem morphemes from fully concatenated complex forms. As opposed to affixes, stems are free-standing morphemes that can be mapped onto existing representations in the mental lexicon and therefore do not require a specialized morphological chunking mechanism (Grainger & Beyersmann, 2017). Grainger and Beyersmann (2017) therefore argue that the mechanism by which stems are recognized is distinct from the mechanism by which affixes are being identified. Given their high exposure to compound words, we reasoned that Germans might develop certain proficiency at mapping embedded stems onto existing lexical representations, which will likely be reflected in more robust stem-identification effects in German than in French.

Present study

To test differences in morphological processing between the visual and auditory modality in French and German we used an experimental paradigm that allowed us to tightly control for both item- and language-specific variables. We conducted an auditory and a visual lexical decision task using the same translation-equivalent items in both tasks. We focused on the processing of morphologically complex nonwords by manipulating orthogonally the stem and the suffix. In particular, four conditions were created: Stem + Suffix (e.g., *nuit* + *eur* = *nuiteur*, *Nacht* + *er* = *Nachter* [engl. nighter]), Stem + Non-Suffix (e.g., *nuit* + *erge* = *nuiterge*, *Nacht* + *atz* = *Nachtatz*; where *erge* and *atz* are non-morphemic endings in French and German, respectively [engl. nightel]), Non-Stem + Suffix (e.g., *nait* + *eur* = *naiteur*, *Necht* + *er* = *Nechter*; where *nait* and *Necht* are nonwords [engl. naghter]), and Non-Stem + Non-Suffix (e.g., *nait* + *erge* = *naiterge*, *Necht* + *atz* = *Nechtatz* [engl. naghtel]). The primary advantage of this 2x2 design was that it allowed to tease apart the separate roles of the stem and the suffix, as well

as their interactions. The selection of nonwords provided greater control over psycholinguistic variables that are known to influence language processing (e.g., word frequency).

Previous studies

It is worth noting that a number of studies in this research domain have included complex nonwords in their investigations, but these have been typically restricted to the comparison between Non-Stem + Affix vs. Non-Stem + Non-Affix (Lavric, Elchlepp, & Rastle, 2012; Zweig & Pylkkänen, 2009), Stem + Affix vs. Non-Stem + Affix (Taft & Forster, 1975), Non-Stem + Suffix vs. Non-Stem + Non-Suffix vs. Stem + Non-Suffix (Vannest, Newport, Newman, & Bavelier, 2011), or Stem + Suffix vs. Stem + Non-Suffix (Beyersmann et al., 2019; Dawson, Rastle, & Ricketts, 2018). What these prior studies concurrently show is that the presence of morphemes in nonwords makes the process of rejecting a nonword in lexical decision harder, a finding that has been typically referred to as the “morpheme interference effect” (Taft & Forster, 1975). However, what these studies were less able to address are the combined effects of stem and affix, because of the absence of a full factorial design.

Hypotheses

In sum, the present study investigated how morphological processing might differ in the visual and auditory modality as a function of the morphological productivity of a language. We hypothesized that a suffix-effect would be evidenced by slower reaction times (RTs) and higher error rates in the Suffix compared to the Non-Suffix conditions, whereas a stem-effect would be evidenced by slower RTs and higher error rates in the Stem compared to the Non-Stem conditions. This is because the presence of a suffix and/or a stem in nonwords should make their rejection harder during lexical decision. The combined stem- and suffix-effects should further result in a significant Stem-by-Suffix interaction, because the stem-effect would be larger for

suffixed than for non-suffixed nonwords. We also expected more robust stem- and suffix-effects in the visual compared to the auditory modality (i.e., evidenced by significant Stem-by-Modality and Suffix-by-Modality interactions), because morphological structure is more consistently represented in print than aurally. Moreover, on the assumption that the morphological productivity of a language influences the degree of morphological processing both visually and aurally, we hypothesized that morphological processing, and in particular embedded stem recognition, should be more robust in German than in French (i.e., evidenced by a robust Language-by-Stem interaction). On the assumption that morphological productivity in German is attributed to its rich compounding rather than its derivational system (Sadeniemi et al., 2008), it was less clear whether a Language-by-Suffix interaction would also emerge. If anything, this should be weaker or smaller in size than the Language-by-Stem interaction. Finally, as a by-product of our key hypotheses listed above, it was further predicted that the additive weight of the larger morphology effects in the visual modality, and the larger morphology effects in the German language, would result in an overall larger modality effect in German (evidenced by a significant Language-by-Modality interaction), as well as larger morphology effects in the visual modality in German (evidenced by a significant Language-by-Modality-by-Stem interaction, and possibly a significant Language-by-Modality-by-Suffix interaction).

Experiment

Method

Participants. A total of 96 adults, 48 French (4 males, 5 right-handed, Mean Age = 19.0, SD = 1.7) and 48 German (11 males, 5 left-handed, Mean Age = 24.7, SD = 3.8) participated in the study for monetary compensation. Participants were native speakers of their respective language, had normal or corrected-to-normal vision, and reported no hearing, reading, or

language difficulties. Five French participants were bilingual (French-Italian, French-Portuguese, or French-English) and one was trilingual (French-Malagasy-English). Two German participants were bilingual (German-English, German-Bulgarian). The study was approved by the ethics committees of Aix-Marseille Université and the Max Planck Institute for Human Development, for the French and German participants, respectively. Prior to participating in the study, participants provided written, informed consent. Each participant completed both the visual and the auditory lexical decision task, while the order of the tasks was counterbalanced across participants.

Materials. Sixty morphologically simple words corresponding to translation-equivalent nouns (e.g., *nuit*, *Nacht* [engl. night]), which often happened to be cognates (e.g., *film*), were selected from each language. These 60 words served as stems and were combined with five noun-forming, translation-equivalent suffixes in the two languages to form morphologically structured and non-morphologically structured nonword targets (see Table 1 for details concerning the selected suffixes). The French and German suffixes were matched as closely as possible on number of letters ($M = 3.6$, $SD = 0.5$ vs. $M = 3.4$, $SD = 0.6$; $t(4)=0.54$, $p = .621$), number of phonemes ($M = 2.0$, $SD = 0.6$ vs. $M = 2.8$, $SD = 0.6$; $t(4)=1.37$, $p = .242$), and logarithmic suffix frequency¹ ($M = 3.2$, $SD = 0.3$ vs. $M = 2.9$, $SD = 0.5$; $t(4)=2.43$, $p = .072$), for French and German, respectively.

¹ Suffix frequencies were extracted from CELEX (Baayen, Piepenbrock, & van Rijn, 1993) for German and Lexique (New, Pallier, Brysbaert, & Ferrand, 2004) for French. We note however that the suffix frequency measures for the two languages are not directly comparable, because the size of the corresponding corpora and the morphological segmentation methods that were used in each case differed.

Table 1. Translation equivalent French and German suffixes and their meanings.

German	French	English*	Examples (German; French)	Suffix meaning
ung	ion	ion	Trennung; separation (Engl. separation)	(result of) an action or process
bar	able	able	ersetzbar; remplaçable (Engl. replaceable)	able to be done; suitable; subject to
keit	ment	ment	Dankbarkeit, remerciement (Engl. acknowledgement)	action or result of what is denoted by the stem
er	eur	er	Arbeiter, travailleur (Engl. worker)	forms agent nouns from the stem
haft	eux	ful	zweifelhaft; douteux (Engl. doubtful)	possessing the quality expressed by the stem

*English translations are provided for reporting purposes only.

Stems were either combined with suffixes, forming nonwords in the Stem + Suffix condition (e.g., *nuiteur*, *Nachter* [engl. nighter]), or a letter sequence that did not correspond to a suffix, forming nonwords in the Stem + Non-Suffix condition (e.g., *nuiterge*, *Nachtatz* [engl. nightel]). After a letter was replaced in these stems, the resulting non-stems (i.e., nonwords) were combined with the same suffixes, forming nonwords in the Non-Stem + Suffix condition (e.g., *naiteur*, *Nechter* [engl. naghter]), or the same letter sequences, forming nonwords in the Non-Stem + Non-Suffix condition (e.g., *naiterge*, *Nechtatz* [engl. naghtel]). In addition, sixty words that also corresponded to translation-equivalent nouns in the two languages were selected and included in the study for the purpose of the lexical decision task. Half of these words, which often happened to be cognates too, were suffixed, hence morphologically complex (e.g., *boulangier*, *Bäcker* [engl. baker]), while the remaining half were non-affixed (e.g., *diamant*, *Diamant* [engl. diamond]), hence morphologically simple.²

² Due to an oversight, three German non-suffixed words (*Bescheid*, *Existenz*, *Frisur*) were originally incorrectly chosen as suffixed. However, for the calculation of the psycholinguistic properties of the items and the analyses, these items were classified as non-suffixed.

Word frequency and Orthographic Levenshtein distance (OLD20: Yarkoni, Balota, & Yap, 2008), were extracted from Lexique (New et al., 2004) for French, and SUBTLEX-DE (Brysbaert et al., 2011) for German, both of which use film subtitles to calculate word frequencies.³ The OLD20 is given by the number of edits (insertions, deletions, and substitutions) required to transform one word into another, and is based on the average edit distance of the 20 nearest neighbors in the lexicon. The higher the OLD20 value of a word or a nonword, the sparser its orthographic neighborhood. All items are shown in the Appendix and their psycholinguistic properties are displayed in Tables 2 and 3.

Both the French and the German auditory targets were produced with the OS X Speech Synthesizer. The naturalness of the synthesized files was checked by two independent native speakers in each language. Auditory files were edited to ensure that any silence at the beginning and end of each item was removed.

Table 2. Psycholinguistic Properties of French and German Nonwords (SDs in Parentheses).

Nonwords	Stem+Suffix	Stem+Non-Suffix	Non-stem+Suffix	Non-stem+Non-Suffix
French				
OLD20	2.5 (0.6)	2.9 (0.5)	2.7 (0.6)	3.2 (0.6)
N letters	8.1 (1.3)	8.2 (1.1)	8.1 (1.3)	8.1 (1.2)
N phonemes	5.7 (1.3)	6.2 (1.1)	5.9 (1.3)	6.3 (1.2)
German				
OLD20	2.8 (0.6)	2.7 (0.5)	3.0 (0.7)	2.9 (0.5)

³ It is worth noting that just like suffix frequencies, stem frequencies in the two languages cannot be directly compared, because the size of the corresponding corpora are substantially different.

N letters	7.7 (1.2)	7.3 (1.2)	7.7 (1.2)	7.3 (1.2)
N phonemes	6.8 (1.1)	6.8 (1.1)	6.9 (1.1)	6.9 (1.1)
French vs. German				
OLD20	t(59)=-3.555, p = .001	t(59)=2.271, p = .027	t(59)=-3.089, p = .003	t(59)=3.520, p = .001
N letters	t(59)=2.560, p = .013	t(59)=4.597, p < .001	t(59)=2.560, p = .013	t(59)=4.678, p < .001
N phonemes	t(59)=-5.169, p < .001	t(59)=-3.500, p = .001	t(59)=-4.738, p < .001	t(59)=-2.929, p = .005

Table 3. Psycholinguistic Properties of French and German Suffixed Words, Non-Suffixed Words and Stems of Nonwords (SDs in Parentheses).

Words	Suffixed Words	Non-Suffixed Words	Stems of Nonwords
French			
OLD20	2.3 (0.5)	2.0 (0.5)	1.5 (0.4)
N letters	8.1 (1.2)	6.7 (0.8)	4.6 (1.0)
N phonemes	6.4 (1.4)	5.0 (0.9)	3.2 (1.0)
Frequency	4.0 (0.6)	3.7 (0.6)	4.4 (0.9)
German			
OLD20	2.3 (0.5)	2.3 (0.4)	1.4 (0.4)
N letters	7.7 (1.2)	6.7 (0.8)	4.3 (1.0)
N phonemes	6.3 (1.1)	6.2 (1.3)	4.0 (0.9)
Frequency	4.1 (0.5)	3.8 (0.6)	4.7 (0.6)

Procedure. A total of three hundred items (60 words and 240 nonwords) in each language were used in the study. The nonword items belonged to four conditions: Stem + Suffix, Stem + Non-Suffix, Non-Stem + Suffix, Non-Stem + Non-Suffix. The word items belonged to two conditions: Suffixed and Non-Suffixed. Four lists were created with each target word appearing once in every list and each target nonword appearing once across the four lists. Thus, each list comprised 120 items, 60 nonwords (15 with stem + suffix, 15 with stem + non-suffix, 15 with non-stem + suffix, and 15 with non-stem + non-suffix) and 60 words (30 suffixed and 30 non-suffixed). Hence, all conditions were represented in each list. An equal number of participants were assigned to each list. The word and nonword items were presented intermixed. The order of trial presentation within each list was randomized across participants. Six practice items consisting of both words and nonwords were presented to the participants prior to the experimental trials.

Participants were tested individually, seated approximately 60 cm in front of a laptop or a PC monitor in a quiet room. Stimulus presentation and reaction time latencies were controlled by DMDX software (Forster & Forster, 2003). In the visual lexical decision task, participants were told that words and nonwords would appear on the screen one at a time. Participants were then instructed to press “K” if the letter string was a word and “D” if the letter string was a nonword. Items were presented in lowercase letters. However, the first letter of the German items was uppercase, because the first letter of noun forms in German is always written in uppercase. Thus, for consistency, all German items were presented in the same format. Stimuli appeared in white on a black background (20-point Arial font) and remained on the screen for 3000 ms or until participants responded, whichever happened first. In the auditory lexical decision task, participants wore headphones and were told that they would hear a word or a nonword one at a

time. Participants had to press the same buttons as for the visual lexical decision task to indicate whether the item they heard was a word or a nonword. A black cross appeared on a white background while the item was presented aurally, and remained on the screen for 3000 ms or until participants responded, whichever happened first. Reaction times were recorded from stimulus onset. In both tasks, participants were asked to respond as quickly and as accurately as possible.

Analyses

Analyses were performed using (generalized) linear mixed-effects models (Baayen, Davidson, & Bates, 2008) as implemented in the *lme4* package (Version 1.1-20; Bates, Maechler, Bolker, & Walker, 2015) in the statistical software R (Version 3.5.1, 2018-07-02, “Feather Spray”, RCoreTeam, 2018). RTs were log transformed to normalize residuals and were then analyzed using a linear mixed-effects (LME) model. For the error analysis, a generalized linear mixed-effects (GLME) model was created using logit transformation and a binomial link function. The significance of the fixed effects was determined with type III model comparisons using the *Anova* function in the *car* package (Fox & Weisberg, 2011). Post hoc comparisons were carried out using cell means coding and single *df* contrasts with the *glht* function of the *multcomp* package (Hothorn, Bretz, & Westfall, 2008) using the normal distribution to evaluate significance.

The data from both languages and tasks were analyzed together. Given that nonwords were the focus of interest in the present study, we only report the nonword analyses. First we report the RT analyses and then the accuracy analyses. The results from the mixed-effects analyses are provided in Table 4 and the mean model RTs and error rates are displayed in Figures 1 and 2.

Table 4. Summary of Linear Mixed-Effects Analyses for Nonword RTs and Accuracy.

Variables	RTs		Accuracy	
	χ^2	<i>p</i>	χ^2	<i>p</i>
Fixed effects (<i>df</i>)				
Intercept (1)	287390.000	<.001	950.155	<.001
Language (1)	47.243	<.001	1.688	=.194

Results

Reaction Times

Incorrect responses to nonwords (7.1% of the data) were first removed. Any latencies below 200 or above 2000 ms (1.3% of the data) were considered as extreme values and were also removed. Outliers were subsequently removed following the procedure outlined by Baayen and

Milin (2010). In particular, a base model, which included only participants and items as random intercepts, was fitted to the data and data points with residuals exceeding 2.5 *SDs* were removed (0.7% of the data). The LME model included the effect-coded fixed effects of Language (French vs. German), Stem (Stem vs. Non-Stem), Suffix (Suffix vs. Non-Suffix), and Modality (Auditory vs. Visual), as well as their interaction. Trial Order, OLD20, Letter Length, and Phoneme Length (all standardized) were included in the model as covariates. Random intercepts and random slopes for the effects of Stem and Suffix, and their interaction, were used for both subjects and items.

Stem and suffix effects

The main effect of Stem was significant. Nonwords with stems ($M = 922$ ms, $SE = 12$) were responded to significantly slower ($\Delta = -62$ ms, $z = 10.800$, $p < .001$) than nonwords without stems ($M = 861$ ms, $SE = 11$). Also, the main effect of Suffix was significant. Nonwords with suffixes ($M = 904$ ms, $SE = 12$) were responded to significantly slower ($\Delta = -26$ ms, $z = 4.586$, $p < .001$) than nonwords without suffixes ($M = 878$ ms, $SE = 11$). Moreover, the Stem by Suffix interaction was significant. The stem effect for suffixed nonwords ($\Delta = -89$ ms, $z = 10.890$, $p < .001$) was substantially larger than the stem effect for non-suffixed nonwords ($\Delta = -35$ ms, $z = 4.781$, $p < .001$).

Modality effects

The main effect of Modality was significant. Nonwords in the auditory lexical decision task ($M = 1038$ ms, $SE = 13$) were responded to significantly slower ($\Delta = -273$ ms, $z = 78.100$, $p < .001$) than nonwords in the visual lexical decision task ($M = 765$ ms, $SE = 10$). Furthermore, the interaction between Stem and Modality was significant. The stem effect in visual lexical decision ($\Delta = 70$ ms, $z = -12.150$, $p < .001$) was larger than the stem effect in auditory lexical decision ($\Delta =$

49 ms, $z = -6.273$, $p < .001$). Also, the interaction between Suffix and Modality was significant. The suffix effect was significant in visual lexical decision ($\Delta = 54$ ms, $z = -9.390$, $p < .001$), but not in auditory lexical decision ($\Delta = -12$ ms, $z = 1.575$, $p = .115$). Accordingly, the triple Stem by Suffix by Modality interaction was significant. This was because the stem effect was much larger for suffixed nonwords than for non-suffixed nonwords in the visual lexical decision task ($z = 6.035$, $p < .001$), compared to the auditory lexical decision task ($z = 2.188$, $p = 0.029$).

Language effects

The main effect of Language was significant. French participants ($M = 974$ ms, $SE = 18$) were significantly slower ($\Delta = -158$ ms, $z = 6.873$, $p < .001$) than German participants ($M = 815$ ms, $SE = 15$). Critically for the hypotheses tested in the present study, the Language by Stem interaction was significant. The stem effect in German ($\Delta = 69$ ms, $z = 9.580$, $p < .001$) was much larger than the stem effect in French ($\Delta = 52$ ms, $z = 5.925$, $p < .001$). Even though the Language by Suffix interaction only approached significance, post-hoc contrasts revealed that the suffix effect in German ($\Delta = 34$ ms, $z = 4.801$, $p < .001$) was larger than the suffix effect in French ($\Delta = 17$ ms, $z = 1.885$, $p = .060$). In addition, the interaction between Language and Modality was significant. Differences between the visual and aural tasks in German ($\Delta = 284$ ms, $z = -63.580$, $p < .001$) were much larger than differences between the two types of tasks in French ($\Delta = 258$ ms, $z = -47.100$, $p < .001$). As per our predictions, the interaction between Language, Stem, and Modality were significant. Post-hoc contrasts showed that the stem effect was not modulated by type of task in French ($z = 1.635$, $p = 0.102$), but it was significantly bigger in visual than in auditory lexical decision in German ($z = 6.428$, $p < .001$).

Taken together, our results show that morphology plays an important role both visually and aurally. However, morphological influences seem to be more robust in the visual than in the

auditory domain. In addition, morphological processing seems to be more robust in German than in French. Also, compared to French, the observed morphological effects in German are much more prominent in the visual than in the auditory modality.

Figure 1. Lexical Decision Latencies (in Milliseconds) and Standard Errors for Nonwords in Visual and Auditory LDT.

Accuracy

The error analyses were conducted in the same way as for RTs. The GLME model included the same fixed effects and interactions as the LME model, . OLD20, Letter Length, and Phoneme Length (all standardized) were included in the model as covariates.

Stem and suffix effects

The main effect of Stem was significant. Nonwords with stems ($M = 5.0, SE = 0.5$) yielded more errors ($\Delta = 3.3, z = -7.608, p < .001$) than nonwords without stems ($M = 1.7, SE = 0.2$). Also, the main effect of Suffix was significant. Nonwords with suffixes ($M = 5.4, SE = 0.6$) yielded more errors ($\Delta = 3.8, z = -7.844, p < .001$) than nonwords without suffixes ($M = 1.6, SE = 0.2$).

Modality effects

The interaction between Stem and Modality was significant. Nonwords with stems yielded more errors in the visual lexical decision task ($\Delta = 4.3, z = 7.505, p < .001$) than in the auditory lexical decision task ($\Delta = 2.4, z = 4.349, p < .001$).

Language effects

The interaction between Language, Stem, and Modality was significant. Post-hoc contrasts showed that the stem effect was not modulated by type of task in French ($z = -0.598, p = .550$), but it was significantly bigger in visual than in auditory lexical decision in German ($z = -3.247, p = .001$). In addition, the interaction between Language, Stem, Suffix, and Modality was significant. This was because the stem effect for nonwords with and without suffixes was similar across modalities in French ($z = -0.302, p = .763$), but it was much bigger in the visual than in the auditory modality in German ($z = 2.353, p = .019$).

Taken together, the results from the analyses on nonword accuracy showed that morphological effects in German are more prominent in the visual than in the auditory modality.

Figure 2. Accuracy (% Error) and Standard Errors for Nonwords in Visual and Auditory LDT.

Discussion

The present study is the first to investigate morphological processing in different modalities (visual vs. auditory) in a cross-linguistic fashion (French vs. German). To study the combined effect of morphemic stems and suffixes, we focused our investigations on four types of morphologically complex nonwords, namely nonwords consisting of a Stem + Suffix, a Stem + Non-Suffix, a Non-Stem + Suffix, and a Non-Stem + Non-Suffix. Our results revealed robust differences between modalities and languages. We summarize these below.

The first goal of our study was to test the hypothesis that morphological processing may be more prominent in the visual than in the aural modality, given that morphology is represented more consistently in written language (e.g., Desrochers et al., 2017; Landerl & Reitsma, 2005;

Rastle, 2018). Our data support this hypothesis, showing that morphological structure has a greater impact on processing in the visual than in the auditory modality. This was evidenced by significant Stem-by-Modality and Suffix-by-Modality interactions (see Figures 1 and 2). This is a novel finding, not only because the direct comparison between processing of derivational morphology in the two modalities has not been previously made, but also because our experimental design allowed us to clearly dissociate the role of the stem and the suffix in visual and auditory recognition processes. Our data show that the presence of a stem or a suffix made it more difficult to reject a nonword in a lexical decision task, and that this difficulty was greater in the visual than in the auditory domain. This suggests that in the visual modality, stems and suffixes were more rapidly identified and mapped onto existing morphemic representations than in the auditory modality. Therefore, our data provide support for the hypothesis that morphology plays a more prominent role in visual than in auditory word recognition, presumably because of the greater consistency of morphological units in printed form.

In addition, we investigated whether morphological processing is modulated by language-specific differences in morphological productivity. On the assumption that German is more morphologically productive than French (e.g., Juola, 2008; Kettunen, 2014; Sadeniemi et al., 2008), we hypothesized that morphological processing effects would also be greater in German than in French. Our results revealed a significant Language-by-Stem interaction, while the Language-by-Suffix interaction approached significance, showing that the influence of morphology – and in particular stem processing – was more robust in German than in French. This finding was further supported by a three-way interaction between Language, Stem, and Modality, which was significant both in terms of response latencies and accuracy (see Figures 1 and 2). The significantly larger stem effect in German compared to French indicates that German

speakers are more proficient in rapidly extracting embedded stems, and this seems to be particularly robust in the visual domain. Our data thus suggest that the lexical system benefits from repeated exposure to morphological regularities, as it is the case in morphologically productive languages like German. We speculate that the productivity of the compounding system, for which German stands out as being one of the most productive amongst Indo-European languages, might be the reason why stem extraction is effortless in this language.⁴

One question that arises from the present findings is whether the identification of stem morphemes and affixes is based on the same core processing mechanisms, or whether the two types of morphemes have an entirely different status in the word recognition system. The first option is that the processing of stems and affixes is governed by the same morphological chunking mechanisms, but that the efficiency of the mechanism is determined by how frequently stems and suffixes are used within a specific language context. This is in line with theories suggesting that morphologically complex words (e.g., *farmer*) are initially “decomposed” and mapped onto specialized morphemic representations (e.g., the stem *farm* and the suffix *-er*), which are then in turn used to generate the combined meaning of the whole word (e.g., Baayen & Schreuder, 1999; Beyersmann, Coltheart, & Castles, 2012; Crepaldi, Rastle, Coltheart, & Nickels, 2010; Diependaele, Sandra, & Grainger, 2009; Taft, 2003). However, on the assumption

⁴ It is worth noting that in a recent cross-linguistic study that investigated morphological effects on reading aloud as a function of the orthographic consistency and morphological complexity of a language (Mousikou et al., 2019), we observed that it is the orthographic consistency of a language, rather than its morphological complexity, that influences morphological processing in reading aloud. However, the consistency with which letters in a certain language map onto phonemes is critical for reading aloud, which could explain why this particular language characteristic influenced morphological processing in this task over and above morphological complexity.

that stems and affixes are handled by the same kind of decompositional mechanism and are therefore closely associated, it is more difficult to explain why the observed cross-linguistic differences in the stem effect were more robust than those in the suffix effect.

The alternative option is based on a more recent proposal by Grainger and Beyersmann (2017) who argued that stems and suffixes are processed in different ways. While affixes always occur in combination with a stem morpheme, stems themselves can occur as free-standing lexical units and therefore do not require setting up any specialized morphological representations (see also Beyersmann & Grainger, 2018). As such, stems can be activated simply by mapping embedded stems onto existing whole-word representations in the lexicon. This idea finds support in recent evidence from masked priming data in the lexical decision task, showing that embedded stems are rapidly activated independently of whether they are accompanied by a suffix or a non-morphemic ending (e.g., Beyersmann, Casalis, Ziegler, & Grainger, 2015; Beyersmann, Cavalli, Casalis, & Colé, 2016; Beyersmann et al., 2018; Hasenäcker, Beyersmann, & Schroeder, 2016; Heathcote, Nation, Castles, & Beyersmann, 2018; Morris, Porter, Grainger, & Holcomb, 2011; Mousikou & Schroeder, 2019; Taft, Li, & Beyersmann, 2018). Suffixes on the other hand require a specialized chunking mechanism by which they are identified and removed from the rest input signal. The identification of an affix then sends in turn an activation boost to the embedded stem, which explains why masked priming studies with affixed and pseudo-affixed words (e.g., Longtin et al., 2003; Rastle & Davis, 2008; Rastle et al., 2004) typically show more priming to their embedded stems (e.g., *farmer-farm* and *corner-corn*) than non-affixed control words (e.g., *cashew-cash*). On the assumption that stems and affixes are handled by two entirely different mechanisms, this theoretical framework is in a better position to explain the presence of a significant Language by Stem interaction (i.e. a bigger stem effect in German than in French) in

the absence of a significant Language by Suffix interaction. Stem-stem combinations form a central component of the German lexical system due to the productivity of the compounding system. Naturally, repeated exposure to compound words would then lead to the development of an efficient routine procedure to rapidly map embedded stems onto existing representations in the mental lexicon, while leaving the affix-chunking mechanism unaffected. Hence, Grainger and Beyersmann's (2017) theoretical framework provides an explanation for the present findings.

Finally, the results revealed an expected main effect of modality, showing that responses were overall slower in auditory than in visual lexical decision. While the visual system can perform a quick initial form-based analysis of the letter string, the seriality of the spoken input imposes a minimal time for word identification. A key follow-up of the current investigation would therefore be the examination of prefixed nonwords, to test if modality differences are replicable when the seriality of stem and affix is reversed. The main effect of language was also significant, showing that German participants responded overall faster than French participants, and so was the language-by-modality interaction, indicating greater language differences in the visual modality. French has less consistent print-to-sound and sound-to-print mappings than German (Ellis et al., 2004; Seymour, Aro, & Erskine, 2003). Thus, differences in response latencies between the two samples could be due to the substantial number of silent letters in the French nonwords (compare number of letters to number of phonemes for French in Table 2). The presence of silent letters in the French nonwords would likely increase the uncertainty of print-to-sound and sound-to-print mappings in this language, thus slowing down decision times in the French sample.

In sum, the present data provide a broader cross-modality and cross-linguistic perspective on the mechanisms involved in morphological processing. The greater impact of morphology within the written modality, which we hypothesize is likely due to the greater consistency of morphology in print, suggests that adults clearly benefit from morphological knowledge during reading. Moreover, the observed cross-linguistic differences in morphological processing demonstrate that language-specific characteristics can influence the cognitive mechanisms underlying visual and auditory word recognition.

Appendix. Items used in the study.

Nonwords			
Stem+Suffix		Stem+Non-Suffix	
French	German	French	German
brasable	Armbar	brasaste	Armucht
arbrement	Baumkeit	arbrelot	Baumarf
jambeable	Beinbar	jambelot	Beinatz
balaiment	Besenkeit	balailot	Besenau
liteur	Better	literge	Bettarf
foudrement	Blitzkeit	foudrenule	Blitzpern
sangeux	Bluthaft	sangonne	Blutam
lettremet	Briefkeit	lettrenule	Briefmen
paineux	Brothaft	painache	Brotarf
seineur	Bruster	seinate	Brustekt
busion	Busung	busuque	Busarf
toiteur	Dacher	toitipe	Dachpfen
glacable	Eisbar	glacenule	Eismen
champeux	Feldbar	champonne	Feldatz
filmeux	Filmhaft	filmuque	Filmarf
volment	Flugkeit	volige	Flugucht
halleux	Flurbar	hallache	Flurpern
facement	Gesichtkeit	facenure	Gesichtarf
fantôment	Gespenskeit	fantômenule	Gespenspern
arrêment	Haltkeit	arrêtepe	Haltarf
boision	Holzung	boisipe	Holzat
pouletable	Huhnbar	pouletème	Huhnam
chienion	Hundung	chienaste	Hundat
biscuitable	Keksbar	biscuitil	Keksmen
garsable	Kerlbar	garsare	Kerlmen
têtement	Kopfkeit	têtelot	Kopfekt
troument	Lochkeit	trounure	Lochucht
airement	Luftkeit	airenure	Luftucht
sourisment	Mauskeit	sourisise	Mauspern
laitment	Milchkeit	laitope	Milcharf
lunement	Mondkeit	lunelot	Mondatz
nuiteur	Nachter	nuiterge	Nachtatz
nidion	Nestung	nidil	Nestarf
parcable	Parkbar	parcache	Parkarf
chevalion	Pferdung	chevalème	Pferdam
pointment	Punktkeit	pointerge	Punktam
rouement	Radkeit	rouenure	Radam
droiteux	Rechtbar	droitate	Rechtmen

jusion	Saftung	jusache	Saftmen
sablion	Sandung	sablenule	Sanducht
trésorion	Schatzung	trésorisse	Schatzarf
sension	Sinnung	sensare	Sinnau
pistement	Spurkeit	pistenure	Spurnauf
pierrement	Steinung	pierrenule	Steinam
fronteux	Stirnbar	frontaste	Stirnatz
jourable	Tagbar	jourouse	Tagucht
tapisable	Teppichbar	tapisisse	Teppichatz
tablement	Tischkeit	tablenure	Tischarf
poteux	Topfbar	potare	Topfekt
tunnelion	Tunnelung	tunnelipe	Tunnelau
mureux	Wandbar	murouque	Wandekt
mondement	Weltkeit	mondenure	Weltekt
ventable	Windbar	venterge	Winducht
blaguement	Witzkeit	blaguipe	Witzarf
loupeux	Wolfhaft	loupouse	Wolfat
motieux	Worthaft	motige	Wortpern
denteur	Zahner	dentaste	Zahnarf
tempsable	Zeitbar	tempsouse	Zeitam
tentement	Zeltkeit	tentenure	Zeltat
traineux	Zughaft	trainaste	Zugat

French	German	French	German
brusable	Arfbar	brusast	Arfucht
aubrement	Baufkeit	aubrelot	Baufarf
jombeable	Beunbar	jombelot	Beunatz
bavaiment	Belenkeit	bavailot	Belenau
lateur	Botter	laterge	Bottarf
foidrement	Blatzkeit	foidrenule	Blatzpern
sargeux	Blethaft	sargonne	Bletam
lottrement	Bliefkeit	lottrenule	Bliefmen
paimieux	Bromhaft	paimache	Bromarf
seifeur	Bluster	seifate	Blustekt
bumion	Bumung	bumuque	Bumarf
taiteur	Ducher	taitipe	Duchpfen
glatable	Eusbar	glatenule	Eusmen
chalpeux	Faldbar	chalponne	Faldatz
falmeux	Filthaft	falmuque	Filtarf
vosment	Fluskeit	vosige	Flusucht
holleux	Flerbar	hollache	Flerpern
ficement	Gosichtkeit	ficenure	Gosichtarf
fastôment	Gestenstkeit	fastômenule	Gestenstpern
arvêment	Holtkeit	arvêtipé	Holtarf

boimion	Holmung	boimipe	Holmat
pauletable	Hehnbar	pauletème	Hehnam
chionion	Hondung	chionaste	Hondat
bisfuitable	Kelsbar	bisfutil	Kelsmen
garpable	Kertbar	garpare	Kertmen
têrement	Korfkeit	têrelot	Korfekt
traument	Lechkeit	traunure	Lechucht
aipement	Luptkeit	aipenure	Luptucht
sourifment	Maunkeit	sourifisse	Maunpern
lautment	Mulchkeit	lautope	Mulcharf
luvement	Moldkeit	luvelot	Moldatz
naiteur	Nechter	naiterge	Nechtatz
nedion	Nostung	nedil	Nostarf
parmable	Parmbar	parmache	Parmarf
chetalion	Pfeldung	chetalème	Pfeldam
poiltment	Pulktkeit	poilterge	Pulktam
rauement	Ridkeit	raenure	Ridam
draiteux	Rachtbar	draitate	Rachtmen
julion	Saktung	julache	Saktmen
satlion	Sardung	satlenule	Sarducht
trisorion	Schetzung	trisorisse	Schetzarf
selpion	Sintung	selpare	Sintau
pisfement	Smurkeit	pisfenure	Smurnauf
piurrement	Steunung	piurrenule	Steunam
fronseux	Stirmbar	fronsaste	Stirmatz
jaurable	Tafbar	jaurouse	Tafucht
tupisable	Teplichbar	tupisise	Teplichatz
teblement	Teschkeit	teblenure	Tescharf
pomeux	Tolfbar	pomare	Tolfekt
tunfelion	Tunfelung	tunfelipe	Tunfelau
muleux	Wardbar	muluque	Wardekt
monpement	Woltkeit	monpenure	Woltekt
veltable	Wisdbar	velterge	Wisducht
bleguement	Wetzkeit	bleguipe	Wetzarf
loufeux	Wolphaft	loufouse	Wolpat
mapieux	Wosthaft	mapige	Wostpern
dunteur	Zuhner	duntaste	Zuhnarf
telpsable	Zeilbar	telpsouse	Zeilam
tenfement	Zelpkeit	tenfenure	Zelpat
praineux	Zighaft	prainaste	Zigat
