Abstract:***Objectives***

Describe and evaluate the outcome of COVID patient without shortness of breath

Design and methods

We retrospectively collected data from COVID-19 patients diagnosed and cared for in Marseille France. We selected data from patients who had at admission, a low dose CT scanner, dyspnea status and oxygen saturation available. Blood-gas was analyzed in a sample subset of patients.

Results

Among 1712 patients with COVID-19 we report that 1107 (64.7%) do not complaint of a shortness of breath at admission. The LDCT scan showed signs compatible with pneumonia in 757/1,107 (68.4%) of patients without dyspnea. In a subset of patients who had underwent at least one blood gas analysis (n=161) and presented without dyspnea at admission, 28.1% (27/96) presented with a hypoxemia/hypocapnia syndrome. **Asymptomatic hypoxia** was associated with a very poor outcome (33.3% were transferred to ICU and 25.9% died)

Conclusion

The absence of shortness of breath in old patient with co-morbidity merit medical attention and should not be considered as a good sign of wellbeing. The poor prognosis of **asymptomatic hypoxia**, highlight the severity of this mild clinical presentation. In these patient's pulse oximetry is an important mean to predict the outcome along with news score and LDCT scanner.

1 **Introduction**

2 Recently, a new coronavirus named SARS-CoV-2 emerged in China at the end of
3 December 2019 and rapidly spread throughout the world, producing millions of victims and
4 several hundred thousand deaths (1). The early descriptive reports of the clinical presentation
5 of the disease resulting from SARS-CoV-2 infection, named COVID-19, revealed that a third
6 of patients did not have dyspnea (2). Shortness of breath has been reported in 18.7% of 1,099
7 patients hospitalized with COVID-19, many of whom showed an abnormal CT scan (86%)
8 and received supplemental oxygen (41%) (3). In patients with objective radiographic findings
9 consistent with COVID-19 pneumonia, only 50% report shortness of breath (1). Despite this
10 accumulating knowledge, the criteria for clinical screening and care management in most
11 countries, including France, are still based upon 3 symptoms: fever, cough and dyspnea.
12 Asymptomatic patients are requested to self-isolate at home, while those that become
13 symptomatic are invited to contact their health care provider (4). However, some patients with
14 COVID-19 deteriorate rapidly and seemingly without warning. For example, in Marseille,
15 France, more than two thirds of patients hospitalized in intensive care units (ICUs) come
16 directly from home or are admitted to the ICU after less than three days of standard ward
17 hospitalization. Additionally, many patients who go on to develop respiratory failure
18 experienced hypoxemia and hypocapnia without signs of respiratory distress, especially
19 elderly patients. This is called "happy hypoxemia" or "silent hypoxemia" and was previously
20 described in patients during the initial Wuhan outbreak (5). The cause of this **asymptomatic**
21 **hypoxia** is not yet clear. Anosmia-hyposmia has been reported as a frequent clinical sign in
22 COVID (6) but whether SARS Cov2 access to the brain and contribute to the association
23 between dyspnea and anosmia-hyposmia remained to be determined (7). Some have links
24 happy hypoxemia with the development of thrombi within the pulmonary vasculature (8).

25 The discrepancy between respiratory clinical signs and the pulmonary lesions
26 observed with a low-dose computed tomography (LDCT) scanner were reported in the early
27 epidemic by Chinese authors (1;2;9) but was not taken into account, and decisions based on
28 home interviews of patients only considered dyspnea to justify hospital care. Massive test
29 implementation and careful observation of positive patients, regardless of whether they were
30 apparently symptomatic, allowed us to show that some patients who were classified as
31 asymptomatic actually had hypoxia and others had lung damage visible on CT scan (10). In
32 this work, which is derived from a report based on a cohort of 3,737 patients , we wanted to
33 focus on the relationship between dyspnea, hypoxemia and lung lesions identified in LDCT
34 scans.

35 **Patients and methods**

36 The patients

37 We retrospectively collected data from the information system of our hospital related
38 to COVID-19 patients diagnosed and cared for in the infectious disease institute (IHU
39 Méditerranée Infection) in Marseille France from March 3rd until April 27th. All patient care
40 were diagnosed by PCR of a nasopharyngeal sample and were over 18 y-o (10;11). We
41 selected data from patients who had in their record at admission, all of the following items: a
42 low dose CT Scanner, dyspnea status and oxygen saturation available (1,712 patients). Blood-
43 gas were analyzed in a sample subset (161 patients). Dyspnea is a subjective sign which was
44 recorded at interview and was defined as shortness of breath. O₂ desaturation was defined as
45 SaO₂≤95%. A low-dose CT scanner was proposed for all patients **as soon as possible after**
46 **admission** when possible, and radiological lesions were classified into four categories:
47 normal, minimal grade 1, intermediate grade 2 or severe grade 3 (12). Hypoxemia was
48 defined as pO₂_mmHg≤ 80, and hypocapnia as pCO₂_mmHg≤35. Demographics, chronic
49 conditions (cancer, diabetes **mellitus**, chronic heart disease, hypertension, chronic respiratory

50 disease and obesity), concomitant medication, and signs and symptoms, including fever,
51 cough, anosmia, ageusia, dyspnea, oxygen saturation, and blood gas analysis were extracted
52 from the hospital information system (10) . Severity was assessed using the national early
53 warning score adapted to COVID-19 patients (NEWS-2) (12).

54 Statistics

55 Categorical variables are presented as n (%). We used Chi-squared test, Fisher's exact
56 test, univariate logistic regressions and estimated odds ratios (ORs) with 95% confidence
57 intervals (CIs) to compare differences between patients with dyspnea and patients without
58 dyspnea. To compare the prognosis performance of the LDCT scanner score and O₂ saturation
59 on clinical outcomes (transfer to ICU/death) among patients with no dyspnea, we performed
60 multivariate logistic regressions. Models were adjusted on the following covariates: age, sex,
61 time from symptom onset to admission, comorbidities (cancer, diabetes mellitus, cardiac
62 diseases, hypertension, chronic respiratory diseases, obesity) and clinical classification at
63 inclusion (NEWS score). Four separate models were carried out. In the reference model
64 (model A), all covariates previously listed were included. In Model B, we added to this list
65 the LDCT scanner severity score. In model C, we added O₂ saturation. Model D included both
66 O₂ saturation and the LDCT scanner severity. We calculated the Akaike information criterion
67 (AIC) and computed the C-statistic for each model. The C-statistic is equal to the area under
68 the receiver operating characteristic (ROC) curve and ranges from 0.5 to 1. A two-sided α
69 value of less than 0.05 was considered statistically significant. To investigate associations
70 between clinical data, biological data, radiological data and clinical outcomes (death and/or
71 ICU stay), we performed univariate logistic regressions and Principal Component Analysis
72 (PCA) in a subset of 161 patients who had underwent at least one blood gas analysis.
73 Hierarchical Clustering on Principal Components (HCPC) was performed to identify clusters
74 of patients. Analyses were carried out using SAS 9.4 statistical software (SAS Institute, Cary,

75 NC). PCA and HCPC were performed using R Statistical Software and the FactoMineR
76 package (13).

77 **Results**

78 Among 3,737 patients diagnosed with SARS-CoV-2 infection in our institute, we
79 selected 1,712 with available dyspnea, O₂ saturation and LDCT scan information obtained
80 within the first 48 or 72 hours. Among them, 1,107/1,712 (64.7%) presented with no dyspnea,
81 and 605/1,712 (35.3%) presented with dyspnea. Underlying conditions and clinical symptoms
82 are comprehensively described in **Table 1**. The prevalence of poor clinical outcome (transfer
83 to intensive care unit and/or death) significantly increased among patients with dyspnea.

84 The LDCT scan showed signs compatible with pneumonia in 757/1,107 (68.4%) of
85 patients without dyspnea, with 525/757 (69.4%) of patients exhibiting minimal grade 1
86 lesions, 194/757 (25.6%) of patients exhibiting intermediate grade 2 lesions, and 38/757
87 (5.0%) of patients exhibiting severe grade 3 lesions (**Figure 1, Table 2**). Compared to
88 patients without dyspnea, lesions of grades 2 and 3 were significantly more frequent in
89 patients with dyspnea (OR 95% CI: 1.58; 1.24-2.01 and OR 95% CI: 2.15; 1.38-3.37,
90 respectively). 157/1107 (14.2%) of patients without dyspnea had an O₂ sat ≤95. Among them,
91 84 had an O₂ sat ≤94, 48 had an O₂ sat ≤93, 26 had an O₂ sat ≤92, 12 had an O₂ sat ≤91 and 6
92 had an O₂ sat ≤90. Compared with patients without dyspnea, oxygen saturation was
93 significantly worse in patients with dyspnea (**Table 2**).

94 Among the 1,107 without dyspnea, those which LDCT grade 2 and 3 lesions had
95 significantly higher odds of having a poor clinical outcome during follow-up (OR 95% CI:
96 9.45; 3.02-29.62) (**Table 3**). Compared to the model with O₂ sat (OR 95% CI: 0.78; 0.65-
97 0.93), the model with LDCT scan score achieved a better goodness-of-fit (lower AIC).

98 In the subset of patients who had underwent at least one blood gas analysis (n=161)
99 and presented without dyspnea at admission, 28.1% (27/96) presented with a

100 hypoxemia/hypocapnia syndrome defining **asymptomatic hypoxia** **Figure 2**. HCPC analysis
101 distinguished three clusters. Hypoxemia/hypocapnia syndrome (yellow dots) was clustered
102 with death/ICU, elevated NEWS score, age, male and elevated D-dimers.
103 Hypoxemia/hypocapnia was associated with aging, male, and chronic heart disease but not
104 with diabetes **mellitus**. Hypoxemia/hypercapnia (33%) clustered with favorable outcome and
105 was associated with younger age. Hyperoxemia/ hypocapnia (22%) was associated with
106 women and younger age. Hyperoxemia/hypercapnia (15%) was surprisingly associated with
107 cancer (**Figure 3, Table 4**). Hypoxemia/hypocapnia syndrome was strongly associated with
108 death/ICU (OR 95% CI: 4.37; 2.12-9.03) ($p < 0.0001$) and elevated D-dimers > 2.5 mg/l (OR
109 95% CI: 6.26; 1.99-19.75) ($p = 0.002$).

110 **Discussion**

111 In patient with COVID 19 dyspnea is linked to poor outcome and merit attention and
112 urgent care. However, it is important to underling that among 1712 patients with COVID-19,
113 64.7% (1107) do not complaint of shortness of breath at admission and that 23 of them were
114 transferred to ICU and /or died highlighting the severity of this clinical presentation. In these
115 patients, News score, LDCT of the thorax and pulse oximetry are important means to predict
116 death. Moreover, among patient without dyspnea 28.1% presented with
117 hypoxemia/hypocapnia syndrome (happy or silent hypoxemia) which was also strongly
118 associated with a poor outcome. **Due to inclusion criteria, our studied population was**
119 **significantly more severe and had a longer time from symptom onset to admission suggesting**
120 **a selection bias. Consequently our results cannot be extrapolated to the whole population of**
121 **patients with COVID-19.**

122 To the best of our knowledge, this work is the most comprehensive comparison of
123 dyspneic and non-dyspneic COVID-19 patients and their blood gas analysis results and lung
124 lesion findings visualized on a low-dose CT scan. **Asymptomatic hypoxia** has only been

125 reported recently in COVID-19 patients (5,7). Hypoxia with accompanying hypocapnia
126 generates no sensation of breathlessness, on the contrary, it may feel comfortable (14), and
127 COVID-19 patients do not necessarily appear dyspneic until late in the course of the disease
128 (5). Physicians treating COVID-19 patients, including us, have reported caring for patients
129 who presented well and then suddenly, within a few hours, progressed to severe respiratory
130 distress (14).

131 The subjective sensation of dyspnea is driven by the respiratory center in our brain
132 that is sensitive to increased CO₂ and to a lesser degree, decreased O₂ (7). Our respiratory
133 center can become desensitized as we age and from chronic conditions such as diabetes (15).
134 Patients with diabetes were noted to be 1.8 times more likely to have an impaired ability to
135 perceive respirations than nondiabetic controls. Therefore, it was suggested that patients who
136 are presenting with silent hypoxemia are most likely the elderly and those with chronic
137 diseases and consequently the poorest outcomes. In our cohort, age but not diabetes was
138 associated with dyspnea and hypoxemia. While pulse oximetry is underestimating true
139 pO₂_mmHg, in patient feeling comfortable at admission we show that it predicts well the
140 outcome. As consequence in patient with COVID but without shortness of breath, pulse
141 oximetry should be added to the News score and to LDCT to monitor the care.

142 The incidence of thrombotic complications in ICU patients with COVID-19 infection
143 is remarkably high (16). This has been well established by a recent study of necropsied
144 patients, which reported that although the predominant patterns of lung lesions are diffuse
145 alveolar, damage associated with the presence of platelet-fibrin thrombi in small arterial
146 vessels is consistent with coagulopathy and appears extremely common (17). Hypoxemia and
147 elevated D-dimers strongly suggest that the resulting lung damage is due in part to arterial
148 microemboli and might explain the severity of clinical presentation and the subsequent death.

149 These findings reinforce the recommendation to apply thrombosis prophylaxis in these
150 patients (16).

151 It appears now clear that dyspnea is not a key criterion of initial severity in patients
152 with COVID-19. As recommended by the CDC and many other health policies throughout the
153 world, “Patients with a mild clinical presentation (absence of viral pneumonia and hypoxia)
154 may not initially require hospitalization, and many patients will be able to manage their
155 illness at home” (4). We believe that it is necessary to systematically ask for shortness of
156 breath that is a subjective sensation not related with respiratory frequency and very frequently
157 reported. Among patients feeling well and without dyspnea, a third (28.1%) might present
158 with hypoxemia at admission. This absence of shortness of breath merit medical attention and
159 it should not be considered as a good sign of wellbeing. We suggest that for these patients
160 with “a mild clinical presentation” it is particularly important to achieve in a regular basis
161 oxygen saturation with pulse oximetry completed with blood gas analysis if necessary, to
162 allow early diagnosis of **asymptomatic hypoxia** and a more appropriate care to reduce the
163 poor outcome.

Figure 1: LDCT scan at admission in a patient with silent COVID-19 pneumonia who abruptly needed O₂ support and ICU surveillance for 48 hours and his control LDCT at day 10 of treatment with hydroxychloroquine and azithromycin showing residual lesions with retraction, suggesting fibrosis

Figure 2: Venn diagram showing that in patient presenting with no dyspnea (27/96) 28.1% will have hypoxemia hypercapnia syndrome defining **asymptomatic hypoxia** (161 patients)

Figure 3. Associations between blood gas analysis, clinical data, biological data and clinical outcomes
- Hierarchical Clustering on Principal Components (n=161)

Conflict of interest

None of the authors report a conflict of interest that might interfere with the manuscript contents

Financial support

This study was supported by the National Research Agency under the program «Investissements d'avenir », reference ANR-10-IAHU-03.

Ethical approval

The noninterventional retrospective nature of the study was approved by our institutional review board committee (Méditerranée Infection N°: 2020-021). According to European General Data Protection Regulation No 2016/679, patients were informed of the potential use of their medical data and that they could refuse. The analysis of collected data followed the reference methodology MR-004 registered on N° MR 5010010520 in the AP-HM register.
