## Abstract

Belgian and Swiss media regularly interfere during French elections by releasing exit polls before polling stations close. These foreign media profit from a law forbidding the same behavior by their French counterparts to receive large inflows of web visits from France. We exploit the unusual timing and degree of confidence with which exit polls were released in the second round of the 2017 presidential elections to investigate their effect on voter turnout. Our analysis is based on comparing turnout rates at different times on the election day, in the first and second round, and with respect to previous elections. We find a significant decrease in turnout of around 3 to 4 percentage points after the exit polls' publication which is suggestive of a causal effect, although similar trends were observed in previous elections. The effect is stronger in departments close to the Belgian border shortly after the release of the exit polls. We do not find clear evidence that either candidate benefited from the decrease in turnout, yet we cannot exclude the presence of a small underdog effect which reduced the winning margin by around 1 percentage point.

**Keywords:** Exit polls, voter turnout, underdog effect, bandwagon effect

# 1 Introduction

Elections take place under a given degree of uncertainty concerning the outcome. If the uncertainty is drastically reduced, will citizens still make the effort to vote? We study this question in the context of the 2017 French presidential elections, by exploiting the early release of exit polls by foreign media.

While in France it is forbidden to publish exit polls before polling stations close, foreign media do not abide by this law. In particular, Belgian and Swiss francophone media regularly report exit polls from French elections while voting is still taking place. For tight elections, this information often comes late and is presented with abundant words of caution concerning its precision. However, the circumstances of the 2017 second-round elections, with the exit polls pointing to a landslide victory for Emmanuel Macron<sup>1</sup>, allowed these media to disclose the results earlier and with an unusual degree of confidence. For example, Belgian broadcaster RTBF reported already at 16:00 that, according to the exit polls in their possession, Macron was clearly ahead and would beat Marine Le Pen with at least 60% of the votes. The announcement was quickly picked up by many other foreign media, while polling stations remained open until 19:00 or 20:00.

We use turnout data at 12:00, 17:00 and at end of the day to investigate the effect of this information shock on voting behavior. Voter turnout at 12:00 is not affected by the exit polls' release, while turnout at 17:00 and at end of the day can be. We compare the turnout rates in the second round to those in the first round of the elections, similarly to a difference-in-differences setting. This assumes that citizens vote on average at the same time in the first and second round. In our baseline specifications, we find a significant decrease in turnout with respect to the first round at both 17:00 and at the end of the day, which ranges between 3.1 and 4.1 percentage points. The effect does not change by controlling for rainfall and variation in temperature, which could potentially affect the distribution of voting times between the two rounds.

To validate our results, we compare the trends in turnout to those in the two previous French presidential elections. In 2012 and 2007, the second-round election was more competitive and foreign media reported the exit polls with more conservative claims concerning their precision until a later time in the day. In both years, we observe that the increase in turnout after 12:00 is lower in the second round than in the first. Nonetheless, the triple-differences estimator is significant with respect to the 2012 elections at both 17:00 and at the end of the day, as well as with respect to the 2007 elections at

---

<sup>1</sup>As also forecasted by most opinion polls, whose average result on the day before the election was 61.79% in favor of Macron. See for example [https://en.wikipedia.org/wiki/Opinion\\_polling\\_for\\_the\\_2017\\_French\\_presidential\\_election](https://en.wikipedia.org/wiki/Opinion_polling_for_the_2017_French_presidential_election)

17:00. This suggests that the decrease in turnout in the second round of the 2017 elections is driven at least in part by the exit polls' publication.

These results give credit to theories of voting as an act which is, at least partially, strategic and instrumental, in contrast to theories of voting as a non-strategic decision motivated by civic duty or by a consumption benefit. A similar decrease in turnout has been found in the US in the 1980 elections, which were called in favor of Reagan while polling stations were still open in the Western states (Delli Carpini, 1984), as well as in the 2000 elections, when Florida was called in favor of Bush while polling stations were still open in the Panhandle counties (Lott, 2005). The results are also in line with Morton et al. (2015), who show that in the French overseas territories, before the 2005 electoral reform, voting after exit polls from the mainland had been published decreased turnout by 11 percentage points.

We complement the analysis by checking whether the effect varies geographically or as a function of the preferences expressed in the first round of the election. With respect to geography, the decrease in turnout at 17:00 is stronger for departments that are closer to Belgium, as measured by the distance from the department's capital to Brussels or to the border. The effect at the end of the day goes in the same direction but it is not statistically significant, a result which could be due to the exit polls being transmitted earlier (i.e. between 16:00 and 17:00) in departments that are closer to Belgium. We do not observe different effects in departments close to the border with Switzerland, compared to all other departments.

Concerning differences in voters' preferences, we observe a greater decrease in turnout following the information shock in departments in which Macron was the most voted candidate in the first round, compared to departments in which he was not. The effect corresponds to an additional reduction of 1.1 percentage points and is weakly significant ( $p$ -value: 0.099). On the contrary, the decrease in turnout is not different in departments in which Le Pen was the most voted candidate in the first round, compared to departments in which she was not.

We then looked at departments in which the vote share for the other candidates in the first round was relatively higher. Specifically, given the ideological positions of Macron and Le Pen, left-wing voters could be more tempted by abstention after the exit polls' release, in order to avoid voting for a weakly preferred candidate. We observe indeed that departments with the 50% highest combined share of votes for Benoît Hamon and Jean-Luc Mélenchon - the two major left-wing candidates - have a stronger decrease in turnout. As before, the effect corresponds to a 1.1 percentage points reduction.

Yet, though close to the 10% level, the coefficient is insignificant at conventional levels (p-value: 0.113).

The analysis with respect to the results in the first round informs the debate about the diffusion of opinion polls in the last days of the electoral campaign, as well as that on the early release of exit polls. The standard rationale for banning their publication is that it could alter the election results by affecting asymmetrically the voters of different candidates. Researchers typically distinguish between an underdog or a bandwagon effect, depending on whether the publication of polls give an advantage to the trailing (underdog effect) or to the leading candidate (bandwagon effect). The empirical identification of a causal effect with real elections data is challenging, because voting is secret and because these effects could be driven not only by changes in turnout rates but also by changes in the vote choice.

The literature has traditionally found mixed evidence (see the discussions in Marsh, 1985; McAlister & Studlar, 1991; and Irwin & Van Holsteyn, 2000), confirmed recently by findings of both bandwagons (Hodgson & Maloney, 2013; Kiss & Simonovits, 2014; Morton et al., 2015) and underdog effects (Chatterjee & Kamal, 2021).<sup>2</sup> Based on our results and under the assumption that left-wing voters in the 2017 French elections preferred on average Macron to Le Pen, we cannot exclude a mild underdog effect, according to which Macron's margin of victory could have been slightly higher in the absence of the information shock.

## 2 Context

The 2017 French presidential elections took place on April 23 and May 7 2017. Because none of the 11 candidates won an absolute majority in the first round, a second round was held between the two top candidates, Emmanuel Macron (who had obtained 24% of the votes) and Marine Le Pen (21.3%). Three other candidates received more than 5% of the votes in the first round, namely François Fillon (20%), Jean-Luc Mélenchon (19.6%), and Benoît Hamon (6.4%). In both rounds, polling stations closed at 20:00 in big cities and nearby municipalities, while at 19:00 elsewhere.

While French polling agencies collect regular exit polls data on election days, the law requires French media to not publish them before 20:00. Foreign media do not abide by this rule, and francophone media in Belgium and Switzerland report exit polls along the day, registering a large increase in their

---

<sup>2</sup>These inconclusive results are echoed by the mixed findings in the experimental literature (Levine & Palfrey, 2007; Großer & Schram, 2010; Morton & Ou, 2015) as well as by theoretical work highlighting potential drivers of both effects (Herrera et al., 2016; Grillo, 2017). These contributions also clarify that the empirical observation of a null or weak total effect might be due to different effects offsetting each other rather than to the absence of any effect.

websites' visits from France. Our empirical analysis relies on the timing and the degree of confidence with which exit polls were unusually released in the second round of the 2017 elections. Foreign media typically wait for a reasonable degree of confidence before publishing the first exit polls and present them with abundant words of caution if the predicted advantage is not large. As an example, in the first round of the 2017 election, Belgian broadcaster RTBF predicted early in the day that Macron would win a relative majority but waited until around 19:00 to predict that Le Pen was going to be the other candidate qualified to the second round. In the second round, instead, although mentioning that voting was still ongoing, RTBF reported already at around 16:00 that Macron was predicted to win with at least 60% of the votes, and updated his vote share to 62%-64% at around 16:20.

Other Belgian and Swiss media published similar results at the same time or slightly later, and the news spread quickly to media in other foreign countries as well as on social networks like Twitter. This information shock, which showed an even bigger margin of victory than the one forecasted by most opinion polls in the previous days, could change citizens' motivation to vote later in the day, in an election that appeared to be already decided.<sup>3</sup>

### 3 Data and empirical strategy

Our dataset contains turnout rates, election results for each candidate, and the number of registered voter at the department level in 2017, 2012 and 2007, obtained from the French interior ministry. Voter turnout is measured at 12:00, 17:00 and when polling stations closed. We merged these data with weather information for both rounds of the 2017 elections, by collecting daily rainfall and maximum temperature in each department's capital.<sup>4</sup>

Our baseline specification compares turnout rates before (at 12:00) and after (at 17:00 and at the closing time) the information shock with respect to the first round in the 2017 elections. As in a difference-in-differences setting, we use turnout rates at 12:00 as the pre-period and turnout rates at 17:00 and at the closing time as post-periods, with the first round as the "control group". This assumes

---

<sup>3</sup>Figure 2 in the online appendix gives a sketch of the information release at different times. The exit polls data mentioned by the foreign media are not public information and cannot be independently verified, since they came from French poll agencies, which were subject to the legal ban. The concerned foreign media, however, did publicly defend their sources as reliable, and the data turned out to be correct ex-post in both rounds of the 2017 elections. In our reading of online information, RTBF took a major role in diffusing the exit polls early and in defending this choice, with both the editor-in-chief and the director of information arguing publicly for the general interest of this information, see for example <https://www.rtbf.be/info/monde/detail-presidentielle-francaise-pourquoi-la-rtbf-diffuse-t-elle-les-estimations-de-resultats?id=9587877> and <http://www.slate.fr/story/144044/presidentielle-francaise-jackpot-belge>.

<sup>4</sup>Table 5 in the online appendix presents a few summary statistics of our data.

that, if the exit polls had not been released, voter turnout would have followed the same trend as in the first round. Our baseline estimation is therefore:

$$turnout_{t,r,d} = \beta_1 time_t + \beta_2 round_r + \beta_3 time_t \times round_r + \epsilon_{t,r,d} \quad (1)$$

where  $turnout_{t,r,d}$  measures turnout at time  $t$  in round  $r$  in department  $d$ ,  $time_t$  is the indicator for the post-periods, and  $round_r$  is the indicator for the second round. Standard errors are clustered at the department level and departments are weighted by the number of registered voters. The coefficient of interest is  $\beta_3$ .

It is however possible that different trends in voting times would have emerged between the two rounds even absent the information shock from foreign media. Figure 1 plots the aggregate turnout rates in the 2007, 2012, and 2017 elections. Unlike in 2017, both in 2007 and in 2012 voter turnout was higher in the second round than in the first. In all three elections, the increase in turnout from 12:00 to 17:00 and to the end of the day appears smaller in the second round than in the first round. In both 2012 and 2007, however, given the much tighter competition between the two second-round candidates, foreign media published exit polls with smaller margins of victory and used a more agnostic language concerning their precision until a later time.<sup>5</sup>

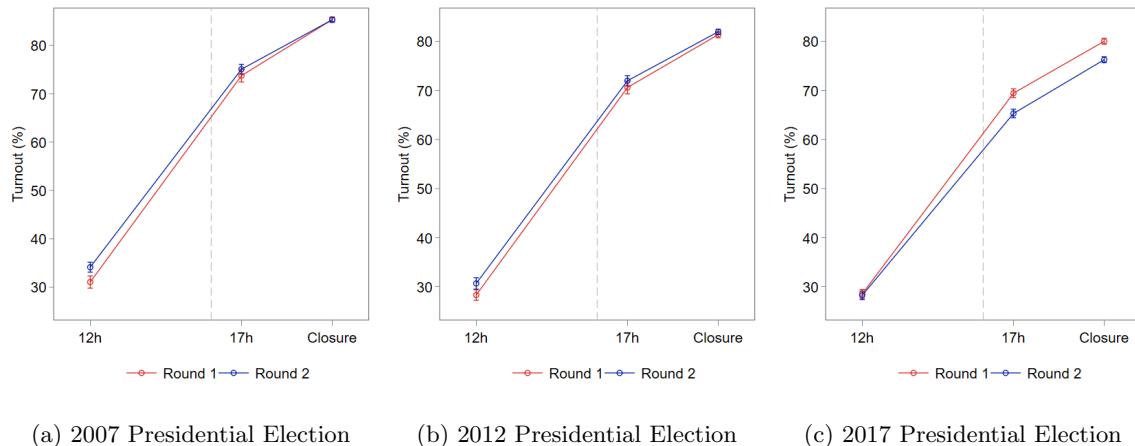

Figure 1: Voter turnout at different times of the day in the first and second round of the French presidential elections.

<sup>5</sup>For example, in 2012 Belgian broadcaster RTBF reported at around 17:20 a predicted vote share of 52%-53% for Hollande against Sarkozy, mentioning the possibility of change. Also, note that polling stations elsewhere than in big cities closed at 18:30 in 2012 and at 18:00 in 2007, while at 19:00 in 2017.

To isolate the effect of the early release of exit polls, we compare the results in 2017 to those in 2012 and 2007 in a triple-differences setting. This analysis assumes that, absent the information shock in 2017, the difference in turnout trends would have been the same as in the two previous elections.

Our second estimation is thus:

$$\begin{aligned} turnout_{y,t,r,d} = & \beta_1 time_t + \beta_2 round_r + \beta_3 year_y + \beta_4 time_t \times round_r + \beta_5 time_t \times year_y + \\ & \beta_6 round_r \times year_y + \beta_7 time_t \times round_r \times year_y + \epsilon_{y,t,r,d} \end{aligned} \quad (2)$$

where  $turnout_{y,t,r,d}$  measures turnout in year  $y$  at time  $t$  in round  $r$  in department  $d$ , and  $year_y$  is the indicator for the year 2017. The coefficients of interest are  $\beta_4$  for the presence of a similar trend in previous elections and  $\beta_7$  for the triple-differences estimation.

## 4 Results

Table 1 shows the results of our baseline analysis. We observe a significant decrease in voter turnout with respect to the first round, following the exit polls' publication. The estimates of the effect are between a 3.4 and 4.1 percentage points reduction in turnout at 17:00 and between a 3.1 and 3.7 percentage points reduction in turnout at the end of the day, depending on the specification. We find that the result does not hinge on weighing departments by the number of registered voters (column 2). The results are also robust to controlling for rain and maximal temperature at the department level (column 3), and hold if we only include departments in which it did not rain (column 4).<sup>6</sup>

In table 2, we compare turnout trends with those in the previous elections. The significant negative coefficients for the interaction between time and round of the election confirm the graphical evidence in Figure 1 of a similar trend in the two previous elections. The coefficients of the triple interaction are however also significant, both at 17:00 and at the end of the day for the 2012 election as well as at 17:00 for the 2007 election. This suggests that despite the similar trend in voting times in previous elections, the information shock contributed to the decrease in turnout from the first to the second round of the 2017 elections. Specifically, with respect to the 2012 elections, the results show that the exit polls' release is associated to an additional decrease in turnout of 2.8 percentage points at 17:00 and of 1.7 percentage points at end of the day.

---

<sup>6</sup>We report the coefficients of all the weather controls in Table 6 in the online appendix as well as the comparison between departments where it never rained and those where it rained (which is insignificant). We note that on the day of the first round elections it rained (lightly) only in one department's capital; hence all raining variation comes from the second-round elections.

## 5 Heterogeneous Effects

In this section, we investigate possible heterogeneous effects along two dimensions, namely geography and the preferences expressed in the first round of the elections. We first examine whether the decrease in turnout is stronger in departments that are closer to the borders with Belgium and Switzerland, the two countries with francophone media which regularly publish exit polls during the election day. The rationale is that voters in departments closer to either country might more likely be aware of the exit polls' release. Moreover, some foreign media like RTBF have a radio station whose signal is received in the French departments that are close to the border. Some voters in these departments could therefore be reached in addition to those who actively look for the information online.

Table 3 shows the results of this analysis. For either border, we distinguish between a first set of very close departments and a second larger set of close ones. These include the 4 and 7 closest departments to either Belgium or Switzerland, respectively.<sup>7</sup> Columns 1 and 2 in Table 3 show a significantly greater decrease in participation for the departments close and very close to Belgium, while columns 3 and 4 show that departments close and very close to Switzerland do not significantly differ from all the others. For the Belgian border, the coefficients of interest are negative for turnout measured both at 17:00 and at the end of the day, although only the one at 17:00 is statistically significant. Their magnitude varies between -1.3 and -2.1 percentage points. One possible line of interpretation for the effect being significant only at 17:00 is that the information shock spread earlier to departments who are closer to Belgium, and then more homogeneously to the whole country by the end of the day.

As a second exercise, we investigate the presence of heterogeneous effects with respect to the preferences expressed in the first round of the elections. This analysis points to the main concern of the early release of exit polls, namely that its effect on turnout could be biased in favor of one candidate and therefore alter the representation of the electorate's preferences. Table 4 reports the results. Column 1 shows that, by the end of the day, the decrease in turnout with respect to the first round was greater in departments in which Macron had won a relative majority in the first round, as compared to all other departments. With a p-value of 0.099, this effect is significant at the 10% level. Its magnitude corresponds to an additional decrease of 1.1 percentage points in turnout. Column 2 shows instead the absence of heterogeneous effects when we compare departments in which Le Pen

---

<sup>7</sup>Figure 3 in the online appendix shows these departments on a map.

had won a relative majority in the first round with all the others.<sup>8</sup>

We then look at whether the decrease in turnout was stronger in departments in which many voters did not support any of the two second-round candidates. Specifically, given the ideological positions of Macron and Le Pen, voters with left-wing preferences could be more likely to opt for abstention after the information shock, instead of voting for a candidate that was only weakly preferred. In column 3 of Table 4, we find that we cannot exclude such an effect for the turnout measure at 17:00. Departments which in the first round had the top 50% joint vote share for Benoît Hamon and Jean-Luc Mélenchon show a larger decrease in turnout after the information shock, compared to departments with the bottom 50% vote share for the two left-wing candidates. As before, the effect corresponds to an additional reduction in turnout of 1.1 percentage points. Though insignificant on conventional levels, with a p-value of 0.113, this effect is close to the 10% level. Finally, column 4 in Table 4 shows the absence of heterogeneous effects between departments with the top and bottom 50% vote share in favor of François Fillon, whose ideological position on the right was in between Macron and Le Pen.

Overall, with respect to the worry that exit polls might alter the representation of preferences through voter turnout, our results point, if anything, to a small underdog effect. In our data, this effect is driven by a greater - but with a weak statistical significance - decrease in turnout in departments in which Macron had won a relative majority in the first round as well as in departments in which left-wing candidates had obtained a higher vote share. We do not find, instead, any evidence suggesting that supporters of the expected loser might abstain at a larger rate.

## 6 Conclusion

On French election days, francophone foreign media in neighboring countries regularly release exit polls in order to attract online readers from France, where the publication of such information is forbidden until voting is over. Whether this early release of information has an impact on the electoral outcome is of key importance to safeguard a fair electoral process. We exploited the circumstances of the 2017 second-round presidential elections to investigate this issue. A predicted landslide victory of Emmanuel Macron against Marine Le Pen allowed the concerned media to release the exit polls earlier than usual and to present the election as *de facto* decided even if voting was still taking place. By comparing turnout rates at different times in the day with respect to the first round and to previous elections, we

---

<sup>8</sup>In the first round, Macron won a relative majority in 41 departments, while Le Pen won a relative majority in 46 departments. Figure 4 in the online appendix shows the geographical distribution of such departments.

estimate a reduction of 3.1-4.1 percentage points in turnout from the exit polls' release.

Consistently with Belgian media being a major source of the information shock, the reduction in turnout affects the departments close to the Belgian border earlier, before spreading more homogeneously across the country. The decrease in participation also seems to have involved Macron's supporters and left-wing voters in the first round more than Le Pen's supporters and right-wing voters. While the magnitude and statistical significance of the effect suggests that the heterogeneity has not been severe, the possibility of altering the true representation of preferences calls for attention on such electoral interference as well as for further investigation of its empirical relevance.
